

Propertizing Environmental Attributes

Katrina M. Wyman[†] & Adalene Minelli^{††}

Tangible environmental resources such as land and water have been the object of property rights and traded in markets for millennia. In a development largely unnoticed by legal scholars, technology now allows a new class of environmental resources that are much harder to see and touch to be measured and potentially sold—environmental attributes. Some of these resources have already been partially packaged into property rights for sale by some governments and private actors, such as actual and avoided carbon emissions, and the environmental benefits of renewable power and electric cars. However, other resources, such as avoided water use, remain unpropertized. Trading environmental attributes can help to achieve important societal objectives, such as decarbonizing the energy system, although there are also criticisms of using markets for these goals.

This Article emphasizes that property rights need to be created in environmental attributes if policymakers and private actors wish to enlist markets to achieve societal goals. The Article explains the steps involved in creating property rights in environmental attributes. Drawing on the approaches already used to create property rights in some of these attributes, the Article identifies a menu of options for establishing property rights in attributes that currently can be measured and those that technology will allow to be isolated in the future. In addition, it applies this menu to recommend a first-in-time rule for establishing property rights in avoided electricity use from energy-efficient appliances and other energy saving measures, a prominent example of the recently recognized class of environmental attributes. Recognizing society's growing interest in harnessing newer environmental attributes, this Article concludes that markets in such attributes could expand if the rules for initially allocating these resources were clarified.

Introduction

Suppose thousands of homeowners buy the most energy-efficient refrigerators available on the same day. With the help of modern technology, the energy use avoided from the installation of these refrigerators can now to be quantified and sold into some wholesale electricity markets.¹ Moreover, as a result of an order that the Federal Energy Regulatory Commission (FERC) issued in 2020, there may be a growing number of electricity markets in which avoided energy use could be sold.² However, someone has to initially own the avoided energy use to be able to sell it.³ Complicating matters, there are many parties who might claim initial ownership of the avoided energy use, including the homeowners who bought the refrigerators, the refrigerator manufacturer, the retailers who sold the refrigerators, the electric utility serving the homeowners that may have programs to promote the purchase of energy-efficient appliances, or an aggregator who bundles the avoided consumption and measures and verifies it. How can one or more of these parties acquire rights in the avoided energy use sufficient to sell it?

This Article is about how to initially establish ownership of environmental attributes, such as energy efficiency. Energy efficiency is one example of a general class of environmental resources that are much harder to see and touch than traditional resources such as land, water, and trees, but that may now be measured, due to recent advances in technology. Governments and private actors have already packaged some of these environmental attributes into tradeable instruments, some of which are highly valuable. These include credits for the environmental benefits associated with electric vehicles, credits for actual and avoided greenhouse gas (GHG) emissions, and credits for the production of renewable energy.⁴ Tesla was profitable in 2020 mostly due to the Zero-Emission Vehicle (ZEV), Low-Emission Vehicle (LEV), and other regulatory credits that it sells to other carmakers who buy these credits to comply with federal and state environmental requirements, not the sales of its electric cars.⁵ The State of California has earned billions auctioning greenhouse gas (GHG) allowances that

are bought and sold by private actors.⁶ Private actors routinely sell air travelers offsets to compensate for the GHG emissions from plane travel.⁷ In some U.S. states and the District of Columbia, individuals earn thousands of dollars a year selling Solar Renewable Energy Credits (SRECs) from installing solar panel systems.⁸

Drawing on the experiences of governments and private actors in establishing property rights in some of the new attributes, this Article explains the steps involved in establishing ownership of newly measurable environmental attributes. It also develops a menu of options for initially allocating property rights in currently-unpropriated attributes that technology now allows to be isolated and sold.

To illustrate how this menu of options might be applied, this Article turns to the example of energy efficiency and recommends a first-in-time rule for initially allocating ownership. Under this rule, the first party—or parties—to package energy efficiency into a saleable format would be deemed to own it. A resource that policymakers and private actors have been seeking to harness for decades, energy efficiency is technologically feasible to isolate and market, provided initial ownership of the attribute is clear. Energy efficiency is already traded in some markets and might be traded more extensively if legal frameworks for initially establishing ownership of it were more widespread. Other environmental attributes also might be easier to trade if the rules for initially claiming them were established using one or more of the options that this Article elaborates for allocating initial ownership.

An important starting point for this Article is that property rights in environmental attributes must be allocated before they can be traded. Trading environmental attributes may further important societal goals, such as reducing GHG emissions or improving electrical grid reliability. However, clarity about who owns environmental attributes is key to facilitating their market exchange. As economist Ronald Coase argued, markets will only operate efficiently if

property rights are well defined.⁹ There is a meaningful risk that uncertainty about who owns environmental attributes will slow the emergence or growth of markets in them. Property law thus plays an important, but underappreciated, role in the development of markets for environmental attributes. As technology continues to evolve, it will be technically feasible to isolate and market more environmental attributes provided law and practice follow suit and property rights are created in the newly separable attributes. If property law does not keep up with these technological innovations, many potentially beneficial market transactions could be stifled.

The Article proceeds in three parts. Part I calls attention to the emergence of a general category of environmental attributes that, due to technological developments, it is now—or soon will be—possible to isolate, measure, and sell. The creation of this new class of resources is not widely appreciated in legal scholarship; scholars have tended to focus instead on individual attributes—such as actual or avoided GHG emissions—without recognizing that they are instances of a broad class of newly measurable environmental resources. To advance scholarship on this new class of attributes, we offer a novel, generic definition of environmental attributes and explain why these attributes can be made the objects of property rights. This Part also discusses some of the benefits and objections to creating tradeable property rights and markets in these new environmental attributes. Part II explains why, as a matter of law and economics, property rights need to be created and allocated in environmental attributes if society wishes to encourage their market exchange. Drawing on the approaches already used to propertize some environmental attributes, Part II further identifies a menu of approaches for initially allocating property rights in environmental attributes to facilitate trade. We discuss how property rights can be created from the top by governments, from below by private actors, and through a hybrid of private and government action. By way of example, Part III applies to energy efficiency the menu identified in Part II and recommends the use of a first-in-time principle to initially allocate ownership of energy efficiency. Part III concludes by emphasizing the potential to use the same or other approaches to initially allocate ownership of other environmental attributes.

Before we proceed, a brief word about what this Article does not address. As explained above, we focus on how property rights can be created and allocated in environmental attributes so that they can be traded. We are not arguing for the creation of property rights and markets in *all* environmental attributes that can be technologically isolated. Whether to use property rights and markets—or other approaches, such as taxes, subsidies, or traditional regulation—to achieve environmental, energy, and other policy objectives is a choice for policymakers, private actors, and ultimately society—a choice that is beyond the scope of this Article. Rather, this Article argues that if policymakers

9. Ronald H. Coase, *The Problem of Social Cost*, 3 J.L. & ECON. 1, 19 (1960).

and private actors do choose to use markets to achieve their goals, property rights need to be established.

I. Background

Over the past several decades, governments and private actors have increasingly recognized a broad array of environmental attributes and facilitated their sale in both regulated and unregulated markets. The attributes that governments have packaged into transferable instruments include allowances for GHG emissions under the carbon trading programs in California¹⁰ and the Regional Greenhouse Gas Initiative (RGGI);¹¹ allowances for sulfur dioxide emissions under the federal Acid Rain Program;¹² Renewable Energy Credits (RECs) denoting a specified amount of renewable energy generation;¹³ and energy savings certificates or credits (“ESCerts,” also known as “white certificates” in the European Union) for energy efficiency improvements.¹⁴ The most notable environmental attributes that private actors have packaged into tradable commodities are avoided GHG emissions, which are currently sold in privately created markets to firms, individuals, and institutions that voluntarily choose to offset their GHG emissions.¹⁵

Although legal scholars are familiar with these various instruments, scholarship has not generally recognized that the environmental resources that these instruments package are discrete instances of a broader class of resources that technology now allows to be measured. This Part defines what we mean when we refer to “environmental attributes” and explains why environmental attributes are suitable objects of property. We then discuss some of the benefits of proptertizing environmental attributes and identify important criticisms of proptertization.

A. Defining Environmental Attributes

Tangible environmental resources such as land have been the object of property rights and traded in markets for millennia. In recent decades, environmental resources that are much harder to see and touch also have come to be traded as advances in technology has allowed these resources to be isolated and measured. We refer to these novel environmental resources as environmental attributes.¹⁶

We define environmental attributes as having three elements. First, environmental attributes have an actual impact on the physical environment. These impacts may benefit the environment, such as avoided GHG emissions which mitigate the effects of climate change, or avoided electricity use, which also may reduce GHG emissions. These kinds of beneficial impacts typically arise from *avoided* consumption of physical resources, such as refraining from clearing a forest that would otherwise have been cut and, therefore, avoiding carbon dioxide emissions.¹⁷ Impacts from environmental attributes also may harm the environment, such as the emission of sulphur dioxide, which contributes to acid rain, or GHG emissions which contribute to climate change. These kinds of harmful impacts typically arise from *active* consumption, such as by burning coal to generate electricity and introducing sulphur dioxide and carbon dioxide into clean air.

Second, environmental attributes can be isolated and distinguished from the object or activity creating the impact—in other words, environmental attributes exist *separately* on their own. For example, producing power from natural gas fueled power plants generates GHG emissions as well as electricity, and these GHG emissions are distinct from the power plants and the electricity. Wind turbines generate both wind energy and avoided carbon emissions, and power purchase agreements for wind energy usually stipulate whether the energy is being sold with or without the environmental attributes.¹⁸ Similarly, producing

16. In using the term “environmental attribute” to encompass a broad class of attributes that spans multiple economic sectors, we depart from the tendency to associate environmental attributes with discrete classes of activity, such as electricity generation. For example, the North American Energy Markets Association defines “environmental attribute” as “an aspect, claim, characteristic or benefit associated with the generation of a quantity of electricity by an electricity generation facility.” *Example Definition for Environmental Attributes*, N. AM. ENERGY MKTS. ASS’N, <https://naema.com/download/88/environmental-attributes-definition/4506/naema-env-attributes-dfnt-final.pdf> [<https://perma.cc/RS35-2AAP>].

17. To use a term popularized by Professor Gretchen Daily and others, the forest provides “ecosystem services” (in this example, carbon storage). “[E]cosystem services [are] . . . the conditions and processes through which natural systems make up, sustain, and fulfil human life.” James Salzman, *What is the Emperor Wearing? The Secret Lives of Ecosystem Services*, 28 PACE ENV’T L. REV. 591, 593 (2011) (referring to Daily’s definition). If measurable, ecosystem services would qualify as a type of environmental attribute; however, environmental attributes are broader than these services, partly because the attributes may come from human activity, not just nature. James Salzman, Genevieve Bennett, Nathaniel Carroll, Allie Goldstein & Michael Jenkins, *Payments for Ecosystem Services: Past, Present and Future*, 6 TEX. A&M L. REV. 199, 225-26 (2018).

18. STOEL RIVES LLP, *THE LAW OF WIND: A GUIDE TO BUSINESS AND LEGAL ISSUES* ch. 7, at 2, 7 (8th ed. 2018). Standard language in REC purchase agreements defines the environmental attributes generated by a renewable energy facility as any “aspect, claim, characteristic or benefit associated with

power from solar panel systems avoids carbon emissions, and these avoided carbon emissions are a distinct attribute sold separately from the panels, and from the power produced.¹⁹ As another example, Tesla generates various environmental attributes in manufacturing and selling electric cars, including avoided GHG emissions and avoided fuel use. These attributes are distinct from the vehicles themselves, and, as mentioned above, these attributes are associated with credits that Tesla sells to other carmakers while selling the cars to consumers.²⁰

Third, environmental attributes can be measured. The ability to measure the attribute contributes to its economic value and allows it to be bought and sold, or otherwise qualifies the holder for incentives, remuneration, or compensation.²¹ An attribute's economic value also may lead parties to invest in measurement technology to realize that value.²² Environmental attributes typically derive their value from others' willingness to pay for them to meet a specific environmental or energy target.²³ Of course, an environmental attribute does not have to have economic value presently to be an environmental attribute—but if it can be measured, it can be monetized.²⁴

the generation of a quantity of electricity . . . other than the electric energy produced.” RENEWABLE ENERGY RES. COMM. & SPECIAL COMM. ON ENERGY & ENV'T FIN., *Master Renewable Energy Certificate Purchase and Sale Agreement*, A.B.A. SECTION OF ENV'T, ENERGY & RES. 5 (2016), https://www.ipa-energyrfp.com/?wpfb_dl=845 [<https://perma.cc/XY4N-5D58>] (emphasis added).

19. Homeowners can even continue to own and sell the SRECs derived from solar panel systems after selling the house with the panels, just as homeowners can take the living room sofa while leaving the living room floor behind. Kerry Thoubboron, *SRECs: Understanding Solar Renewable Energy Credits*, ENERGY SAGE (June 2, 2021), <https://www.energysage.com/solar/cost-benefit/sreccs-solar-renewable-energy-certificates/> [<https://perma.cc/J243-HWLN>].

20. The credits generated by the manufacture of a Tesla could include California's Zero-Emissions Vehicle credits, the U.S. Environmental Protection Agency's (EPA) GHG Emission Standard Performance credits issued under the Clean Air Act, and the U.S. National Highway Transportation and Safety Administration's (NHTSA) Corporate Average Fuel Economy (CAFE) credits issued under the Energy Independence and Security Act. Benjamin Leard & Virginia McConnell, *New Markets for Credit Trading Under US Automobile Greenhouse Gas and Fuel Economy Standards*, 11 REV. ENV'T ECON. & POL'Y 207, 207 (2017).

21. In some cases, registries allow for the efficient identification and tracking of environmental attributes and the underlying conduct associated with them. See, e.g., VERRA REGISTRY, <https://registry.verra.org/> [<https://perma.cc/4BDZ-CCMT>]; AM. CARBON REGISTRY, <https://acr2.apx.com/myModule/rpt/myrpt.asp?r=112> [<https://perma.cc/AW3C-DZ3Y>]; CLIMATE ACTION RSRV. REGISTRY, <https://thereserve2.apx.com/myModule/rpt/myrpt.asp?r=111> [<https://perma.cc/M6H7-6846>]; N. AM. RENEWABLES REGISTRY, <https://apx.com/about-nar/> [<https://perma.cc/EFW8-2TSN>]; W. RENEWABLE ENERGY GENERATION INFO. SYS., <https://www.wecc.org/WREGIS/Pages/Default.aspx> [<https://perma.cc/4949-RR2B>].

22. Harold Demsetz, *Towards a Theory of Property Rights*, 57 AM. ECON. REV. 347, 350 (1967). For example, to obtain REDD+ payments for avoiding GHG emissions through deforestation and forest degradation, countries must invest in “measurement, reporting and verification” of forest conservation measures. Michael Köhl, Prem Raj Neupane & Philip Mundhenk, *REDD+ Measurement, Reporting and Verification – A Cost Trap? Implications for Financing REDD+MRV Cost by Results-Based Payments*, 168 ECOLOGICAL ECON. 106513, 106513 (2020).

23. Environmental attributes may also be valuable for reasons other than their impact on the environment. For example, while energy efficiency is traded in some markets to meet environmental standards, it is also sold into some power markets as an energy resource. See Part IV.

24. Environmental attributes likely exist long before technology enables them to be isolated. For as long as humans have been using wind energy as a source of power rather than fossil fuels, that

B. Environmental Attributes as Objects of Property

Environmental attributes exist even though they cannot always be seen or touched. They are exchanged in markets across the globe because they have been packaged into property rights, either by laws, norms or social practices.²⁵ But, why can environmental attributes be owned and therefore be the objects of *property*?

What constitutes property is an age-old question because the concept of property is fluid.²⁶ There are different definitions of property, and legislatures, courts and scholars often use varying definitions depending on the purpose for which they are defining the term. This Article borrows from a recent draft of the American Law Institute’s Fourth Restatement of Property, which describes property as “rights, obligations, and other legal relations among persons in and through a thing.”²⁷ As this definition of property suggests, the notion of “thinghood” is critical to property—it is, after all, the *thing* that is the focus of the legal relations which the law of property is concerned with.²⁸ Thinghood is apparent for physical items—a book, a car, or a parcel of land are all easily recognizable as constituting things because we can pick them up, move them, or touch them. But *intangible* items, such as novel inventions, can also be things as far as property law is concerned. Thus, having a physical form, while evidence of thinghood, is not a necessary precondition for something to be a legal thing.²⁹

energy has avoided carbon emissions. It is changes in technology that have allowed society to discover, measure, and track—and therefore monetize—environmental attributes such as avoided carbon emissions.

25. Environmental attributes can exist even if they are not packaged into property. For a critical analysis detailing how different assets—including land, nature, and financial assets—historically have been “coded” into capital by law and arguing that this coding has generated wealth and inequality, see KATHARINA PISTOR, *THE CODE OF CAPITAL: HOW THE LAW CREATES WEALTH AND INEQUALITY* (2019).

26. See, e.g., JEREMY WALDRON, *THE RIGHT TO PRIVATE PROPERTY* 26–27 (1990) (noting that there is no “generally accepted account of . . . private property”); Katrina M. Wyman, *The New Essentialism in Property*, 9 J. LEGAL ANALYSIS 183 (2017).

27. RESTATEMENT (FOURTH) OF PROP., vol. 1, div. 1, § 1, at 2 (AM. L. INST., Council Draft No. 1, 2019) [hereinafter RESTATEMENT (FOURTH) OF PROP., Council Draft No. 1]. The 2019 draft is a partial and preliminary draft. The Restatement’s reporters could make changes, and the text that we are drawing on has not been approved by the American Law Institute’s council or its members. The draft Restatement’s definition of property is not materially different from the definition of property in the First Restatement, which also refers to the role of things in property. RESTATEMENT (FIRST) OF PROP., div. 1, ch. 1, introductory note (AM. L. INST. 1936) [hereinafter RESTATEMENT (FIRST) OF PROP.] (“The word ‘property’ is used in this Restatement to denote legal relations between persons with respect to a thing.”); see also RESTATEMENT (FOURTH) OF PROP., Council Draft No. 1, *supra*, vol. 1, div. 1, § 1, at 4 (Reporters’ Note) (“The definition of ‘property’ offered here is similar to the first Restatement’s position that property denotes “legal relations between persons with respect to a thing.”).

28. RESTATEMENT (FOURTH) OF PROP., Council Draft No. 1, *supra* note 27, vol. 1, div. 1, § 1, at 2. See also *id.* vol. 1, div. 1, § 2 cmt. e, at 7 (“Legal thing as necessary but not sufficient condition of property.”). The reporter for the Fourth Restatement, Professor Henry Smith, has emphasized the centrality of thinghood to property in his scholarship. Henry E. Smith, *Property as the Law of Things*, 125 HARV. L. REV. 1691 (2012); Wyman, *supra* note 26, at 194–98.

29. RESTATEMENT (FOURTH) OF PROP., Council Draft No. 1, *supra* note 27, vol. 1, div. 1, § 2 cmt. d, at 6 (“Intangible items, even under some circumstances rights themselves, can be things for purposes of property law, provided they are regarded as a separate whole that is only contingently related to any particular actor.”). The draft Restatement is not breaking new ground in recognizing that property can exist in intangibles. The First Restatement of Property also recognized that intangibles can be the

For the purposes of property law, two primary conditions give rise to legal thinghood. First, the object must be treated as “a separate whole.”³⁰ Second, the object must be “no more than contingently associated with any particular actor,”³¹ meaning it must exist separately from the entity that claims “to possess or own it.”³² Whether an intangible is a thing suitable for property depends largely on the social and economic context in which it exists. As the draft Restatement explains, “Where intangibles are concerned, one cannot draw upon the existence of physical separateness or physical boundaries to help identify things. Consequently, economic and social practice and social norms and customs will play a larger role in delineating things.”³³

Environmental attributes are routinely treated as separate assets from the entity claiming them. They are defined and traded separately from the object generating them, and the practices, norms and customs of the markets in which they are traded dictate that they are only contingently related to the entities which possess them. The fact that environmental attributes have value and can be bought and sold separately from the object or activity generating them, combined with the fact that they can retain that value regardless of the entity possessing them, all point to environmental attributes as proper objects of property.³⁴

In addition to requiring that there be a *thing*, property also requires *ownership*. There are many different views about what ownership entails. Understandings of what it means to own something vary depending on the thing, the time and the place, among other factors.³⁵ Generally speaking, “ownership refers to legal rights to control a thing and everyone else’s correlative duties to

object of property. RESTATEMENT (FIRST) OF PROP., *supra* note 27, div. 1, ch. 1, introductory note. *See also* Katrina M. Wyman, *Property as Intangible Property*, in 1 OXFORD STUDIES IN PRIVATE LAW THEORY 81, 85 n.23 (Paul B. Miller & John Oberdiek eds., 2020) (listing court cases recognizing legal interests in intangibles as property).

30. RESTATEMENT (FOURTH) OF PROP., Council Draft No. 1, *supra* note 27, vol. 1, div. 1, § 2, at 4; *see also id.* vol. 1, div. 1, § 2 cmt. b, at 5 (“In order to be a legal thing an object must be considered a separate and distinct whole.”).

31. *Id.* vol. 1, div. 1, § 2, at 4.

32. *Id.* vol. 1, div. 1, § 2 cmt. c, at 5.

33. *Id.* vol. 1, div. 1, § 2 cmt. d, at 6; *see also id.* (“Common elements that point toward whether an intangible right is regarded as a thing include whether it has value if considered apart from any other thing, whether it consists of mutually complementary attributes, whether it has value without regard to the identity of the person who holds it, and whether it is commonly transferred or bought and sold on a stand-alone basis.”). For a discussion of the academic scholarship on which the draft Restatement is drawing in defining things for property, *see* Wyman, *supra* note 26, at 194-98 (describing the new essentialist understanding of thinghood).

34. While the activities generating some environmental attributes are ongoing, the tradable instruments into which the attributes are packaged are best considered goods, and not services. For example, a carbon offset credit for a reforestation project is predicated on a guarantee by the seller that the GHG reductions derived from the project are permanent, which is to say, that the forest will be maintained. While the activity of maintaining the forest is ongoing, the offset credits are nonetheless best regarded as goods because they guarantee a GHG reduction over the lifetime of the reforestation project. In addition, offsets can be resold, though the same credit should not be used to offset more than one party’s emissions. *Voluntary Credits*, CARBON STREAMING, <https://www.carbonstreaming.com/about-carbon/carbon-offsets/> [https://perma.cc/6675-CJZ6].

35. *See, e.g.*, WALDRON, *supra* note 26, at 47-53 (discussing various approaches to defining ownership); *see also* Wyman, *supra* note 26, at 198-203 (discussing the authority element of the new essentialist definition of property, which is synonymous with ownership).

refrain from interfering with control of the thing.”³⁶ The holders of environmental attributes enjoy a measure of control over these attributes that enables the legal interests in these attributes to be labelled property as between private parties. For example, the holders can—and as we have emphasized, frequently do—transfer these attributes to others. The ability to transfer a resource is often considered an indicium of property.³⁷

As mentioned above, courts, legislatures, and scholars use different definitions of property depending on the context and thus whether a particular interest counts as property will likely be determined by the courts on a case-by-case basis. While there is, for the reasons noted above, a strong case for regarding environmental attributes as proper objects of property between private parties, many existing rights in environmental attributes are unlikely to be considered “private property” protected against governmental takings under the Takings Clause.³⁸ Legislators and regulators often state in the legal frameworks establishing tradable instruments in environmental attributes that the instruments are not property rights. The California³⁹ and Regional Greenhouse Gas Initiative⁴⁰ (RGGI) carbon trading programs, the federal Acid Rain Program,⁴¹ and EPA’s trading program for vehicle carbon dioxide emissions⁴² all include

36. RESTATEMENT (FOURTH) OF PROP., Council Draft No. 1, *supra* note 27, vol. 1, div. 1, § 3, at 9. For discussion of the academic scholarship that helps to inform the draft Restatement’s definition of ownership, see Wyman, *supra* note 26, at 198-203 (explaining the authority element in new essentialist understandings of property).

37. RESTATEMENT (FOURTH) OF PROP., Council Draft No. 1, *supra* note 27, vol. 1, div. 1, § 3, at 9 (“In the case of intangible things, ownership includes the right to license and transfer to the extent allowed by law.”). As an example of how the courts consider the transferability of an item as an indication that it is property, the Federal Circuit considers the ability to trade a permit as an indication that the permit might constitute private property protected by the Takings Clause. *See* Members of the Peanut Quota Holders Ass’n v. United States, 421 F.3d 1323, 1331 (Fed. Cir. 2005).

38. The Takings Clause states “nor shall private property be taken for public use, without just compensation.” U.S. CONST. amend. V. *See generally* Michael Pappas, *Disclaiming Property*, 42 HARV. ENV’T L. REV. 391, 391 (2018) (discussing the implications of legislative property disclaimers on Takings claims). *See also* Cal. Chamber of Com. v. State Air Res. Bd., 10 Cal. App. 5th 604 (2017) (finding that carbon allowances issued by California and subject to a legislative property disclaimer are not property for the purposes of the Takings Clause).

39. CAL. CODE REGS. tit. 17, § 95820(c) (2021) (stating that a carbon dioxide allowance “does not constitute property or a property right”). *But see* Cal. Chamber of Com., 10 Cal. App. 5th at 639 (stating that emissions constitute “valuable property rights”).

40. The eleven states participating in the Regional Greenhouse Gas Initiative (RGGI) have adopted a provision following the RGGI Model Rule, which states “a CO2 allowance . . . does not constitute a property right.” REGIONAL GREENHOUSE GAS INITIATIVE MODEL RULE § XX-1.5(c)(9) (Dec. 14, 2018), https://www.rggi.org/sites/default/files/Uploads/Design-Archive/Model-Rule/2017-Program-Review-Update/2017_Model_Rule_revised.pdf [<https://perma.cc/4NLD-QS27>]. *See* CONN. AGENCIES REGS. § 22a-174-31(b)(E) (2021); 1147 DEL. ADMIN. CODE § 1.5.3.9 (2021); 06-096-156 ME. CODE R. §§ 1(B) & 5(C)(9) (LexisNexis 2021); MD. CODE REGS. 26.09.01.02(B)(20) (2021); 310 MASS. CODE REGS. 7.70(1)(e)(3)(i) (2021); N.H. CODE ADMIN. R. ANN. ENV-A 4605.02(g) (2021); N.J. ADMIN. CODE § 7:27C-1.4(m); N.Y. COMP. CODES R. & REGS. tit. 6, §§ 1.2(17), 1.5(c)(9) (2021); 250 R.I. CODE R. § 120-05-46.7(A)(9) (2021); 16-3 VT. CODE R. § 101(c)(9) (2021); 9 VA. ADMIN. CODE § 5-140-6050(c)(9) (2021).

41. The Clean Air Act, 42 U.S.C. § 7651b(f) (2018) (stating that a sulphur dioxide allowance “does not constitute a property right”).

42. 40 C.F.R. § 86.1865-12(k)(2) (2021) (“There are no property rights associated with CO2 credits generated under this subpart.”).

“disclaimers”⁴³ that these programs’ allowances are not property, though there are also examples of programs without such disclaimers.⁴⁴ Property disclaimers are typically included to preserve governmental flexibility to alter the program—including eliminating allowances entirely—while minimizing the risk of constitutional claims for compensation under the Takings Clause.⁴⁵ The case law on the effects of these property disclaimers is “limited,” but it suggests that they make it more likely that courts will not find government-created permits and allowances to be property protected by the Takings Clause.⁴⁶ However, the courts retain the authority to define property for constitutional purposes,⁴⁷ and therefore such disclaimers are neither sufficient nor necessary to avoid rulings that government-created interests constitute property protected by the Takings Clause.⁴⁸

43. We borrow the apt term from Pappas, *supra* note 38 (referring to “property disclaimers”).

44. Legislation in a small number of states refers to RECs as property. *See, e.g.*, N.H. REV. STAT. ANN. § 362-A:9 (LexisNexis 2021); 52 PA. CODE § 75.1 (2021); P.R. LAWS ANN. tit. 13 § 10421(7) (2021); VT. STAT. ANN. tit. 30, § 8002(26)(B), (26)(C) (West 2021-2022); Todd Jones, Robin Quarrier & Maya Kelty, *The Legal Basis for Renewable Energy Certificates*, CTR. FOR RES. SOLS. 5-6 (2015), <http://resource-solutions.org/wp-content/uploads/2015/07/The-Legal-Basis-for-RECs.pdf> [<https://perma.cc/G3Q7-LLCK>]. Courts have also described some jurisdictions’ RECs as property. *See* Jason A. Schwartz, *Marketable Permits: Recommendations on Applications and Management*, ADMIN. CONF. OF THE U.S. 25 (2017) (citing *In re* Ownership of Renewable Energy Certificates, 913 A.2d 825 (N.J. Super. Ct. App. Div. 2007)), <https://www.acus.gov/sites/default/files/documents/Marketable%20Permits%20Report-final.pdf> [<https://perma.cc/7L2Y-MDF7>]; *Wheelabrator Lisbon, Inc. v. Conn. Dep’t of Pub. Util. Control*, 531 F.3d 183, 190 (2d Cir. 2008)). An EPA website also refers to RECs as property. *State Solar Renewable Energy Certificate Markets*, EPA, <https://www.epa.gov/repowertoolbox/state-solar-renewable-energy-certificate-markets> [<https://perma.cc/9CWG-P53F>]. Moreover, there are no property disclaimers in the regulations establishing the trading programs for NHTSA’s CAFE credits or California’s Zero-Emission Vehicle (ZEV) credits. 49 C.F.R. §§ 500-599 (2021); CAL. CODE REGS. tit. 13 § 1900 *et seq.* (2021).

45. The California Air Resources Board (CARB), which administers the state’s carbon trading program, has explained that the disclaimer is rooted in a desire to avoid claims under the Takings Clause. Supplemental Letter Brief for Respondents at 2, *Cal. Chamber of Com. v. State Air Res. Bd.*, 10 Cal. App. 5th 604 (2017) (No. C075954) (“This statement [that carbon allowances confer no property rights] is necessary to clarify that, vis-à-vis the state, regulatory and enforcement actions taken by [CARB] in implementing the cap and trade program do not give rise to a constitutional takings claim. . . . [A] decision by [CARB]—for enforcement or regulatory reasons—to terminate, revoke or limit compliance instruments should not [create] a loss to the people of California.”) (quotations omitted). A similar desire to avoid claims for compensation under the Takings Clause was behind the Acid Rain Program’s property disclaimer. Heather Jarvis & Wei Xu, *Comparative Analysis of Air Pollution Trading in the United States and China*, 36 ENV’T L. REP. 10234 (2006); LEIGH RAYMOND, PRIVATE RIGHTS IN PUBLIC RESOURCES: EQUITY AND PROPERTY ALLOCATION IN MARKET-BASED ENVIRONMENTAL POLICY 82 (2014).

46. Pappas, *supra* note 38, at 402. *See also Cal. Chamber of Comm.*, 10 Cal. App. 5th at 604; Jarvis & Xu, *supra* note 45, at 10241 (“The legal status of SO₂ pollution trading allowances has never been litigated, and so it remains unclear as to whether the non-property right proclamation would withstand challenge.”). A recent review of the case law confirms this statement.

47. *See, e.g.*, *Cedar Point Nursery v. Hassid*, 141 S. Ct. 2063, 2076 (2021) (emphasizing that the Court will not allow governments to manipulate property rights); *Webb’s Fabulous Pharmacies, Inc. v. Beckwith*, 449 U.S. 155, 164 (1980) (“[A] State, by *ipse dixit*, may not transform private property into public property without compensation.”).

48. *See, e.g.*, *Checker Cab Phila. v. Phila. Parking Auth.*, 306 F. Supp. 3d 710, 744-45 (E.D. Pa. 2018) (finding no protected right to the market value of taxicab licenses although they are described in state law as property); *Joe Sanfelippo Cabs, Inc. v. City of Milwaukee*, 839 F.3d 613, 615 (7th Cir. 2016) (taxi cab permits did not convey right to “control . . . transportation by taxis and taxi substitutes”); *Ill. Transp. Trade Ass’n v. City of Chicago*, 839 F.3d 594, 597 (7th Cir. 2016) (taxi medallions do not provide right to exclude competitors.); *Checker Cab Operators, Inc. v. Miami-Dade County*, 899 F.3d 908,

Importantly, regardless of whether the legal rights that holders enjoy in environmental attributes are considered property protected against governmental takings under the Takings Clause, they are still often considered property as between private parties.⁴⁹ Indeed, in 2017, the Third District Court of Appeal in California expressly stated that California’s state-created allowances authorizing the release of GHG emissions are “valuable, tradable, private property rights” as between private parties,⁵⁰ even though California regulations include a disclaimer that the carbon dioxide allowances “do not constitute property or a property right.”⁵¹ The Court stated that this disclaimer meant the rights are not property for Takings purposes, although they are property as between private parties—and, notably, as against the state for due process purposes.⁵² Often eliding these distinctions, many commentators refer to the allowances and credits that governments have created in environmental attributes as property.⁵³

918-21 (11th Cir. 2018) (noting that although taxicab licenses are described as intangible property in County law, the property interest does not include the right to exclude new competitors).

49. Pappas, *supra* note 38, at 394 (“Disclaimed property is treated as ordinary private property between private individuals, but it is treated as an unprotected interest between individuals and the government . . . Disclaimed property looks like property, acts like property, and appears to be property, except where the government is concerned.”).

50. *Cal. Chamber of Comm.*, 10 Cal. App. 5th at 646-49 (“Although, when read in isolation, these regulations [disclaiming property] could be interpreted to mean that emissions allowances do not constitute property or a property right, when examined in context it becomes clear that this passage refers only to property rights as against the state, not rights as between private parties. A ‘property right’ can mean different things in different contexts . . . [T]he regulations declaring that the allowances confer no property rights preclude an allowance holder from asserting a takings claim *against the State*, but the free alienability of the allowances means they are of value to the *holder*. Indeed, that is the whole point of the ‘trade’ part of the cap-and-trade system, the free alienability of the allowances as between private parties . . . That makes them property for due process purposes, because ‘[t]he right to exclude others, and to sell, assign or otherwise transfer ownership are traditional hallmarks of property.’ . . . As the trial court found, emissions allowances consist of valuable, tradable, private property rights.”) (internal citations omitted).

51. CAL. CODE REGS., tit. 17, § 95820(c) (2021).

52. *Cal. Chamber of Comm.*, 10 Cal. App. 5th at 648-49. The definition of property receiving procedural protection under the Due Process Clause is broader than the test for private property protected by the Takings Clause, and thus more legal interests receive procedural due process than takings protection. See Thomas W. Merrill, *The Landscape of Constitutional Property*, 86 VA. L. REV. 885 (2000).

53. See, e.g., Carol M. Rose, *Rethinking Environmental Controls: Management Strategies for Common Resources*, 1991 DUKE L.J. 1, 27; Daniel Cole, *New Forms of Private Property: Property Rights in Environmental Goods*, in ENCYCLOPEDIA OF LAW AND ECONOMICS 291 (Gerit De Geest ed. 1994); Michael Pappas & Victor B. Flatt, *The Costs of Creating Environmental Markets: A Commodification Primer*, 9 U.C. IRVINE L. REV. 731, 741, 757 (2019); A. DENNY ELLERMAN & DAVID HARRISON, JR., PEW CTR. FOR GLOB. CLIMATE CHANGE, EMISSIONS TRADING IN THE U.S.: EXPERIENCE, LESSONS AND CONSIDERATIONS FOR GREENHOUSE GAS EMISSIONS 38 (2003); TERRY L. ANDERSON & GARY D. LIBECAP, ENVIRONMENTAL MARKETS: A PROPERTY RIGHTS APPROACH 179. See also Schwartz, *supra* note 44, at 25 & n.197 (citing H.R. REP. NO. 101-490, pt. 1, at 366 (1990)) (“Congress also characterized acid rain credits as ‘quasi-property,’ and durable, subject only to limitations or revocations by new legislation passed by Congress and signed by the President.”). However, there are some commentators who might resist the idea that credits and allowances are property rights, perhaps because they take a more essentialist view of what constitutes property. See, e.g., Troy A. Rule, *Entitlement-Shifting Rules*, 62 B.C. L. REV. 1193, 1215-19 (2021) (distinguishing “entitlements” and “property entitlements”).

For non-US perspectives on the status of allowances and credits, see, for example, *Armstrong DLW GmbH v. Winnington Networks Ltd.* [2012] EWHC (Ch) 10, [2013] Ch 156 [50], [58] (Eng.) (describing EU carbon allowances as property in dispute between two private parties); *Deutsche Bank A.G. v. Total Global Steel Ltd.* [2012] EWHC 1201 (Comm) (Eng.) (describing “Certified Emissions Reductions” as “some species of intangible property” in dispute between two private parties (citing *Armstrong, supra*));

C. Benefits and Criticisms of Propertizing Environmental Attributes

There are several policy reasons for propertizing environmental attributes. Commodifying environmental attributes allows society to internalize negative externalities through the development of markets for them, which may reduce pollution more efficiently than traditional forms of command-and-control regulation. For this reason, economists have recommended cap-and-trade programs and other market-based approaches that are premised on the creation of permits entitling holders to undertake a specific activity. Under cap-and-trade, the government establishes a cap on the allowable amount of pollution (such as one ton of sulphur dioxide) that parties can trade to reallocate responsibility for reducing pollution to lower-cost abaters. Several decades of experience with cap-and-trade programs suggest that “well designed” programs are capable of “cost-effectively” reducing pollution, although there are criticisms of these programs as we discuss below.⁵⁴

Creating property rights in environmental attributes also may help to incorporate renewable energy resources (such as solar and wind energy) into the electric grid and to displace fossil fuel sources. Twenty-four states, as well as Washington, D.C. and two U.S. territories, have legally binding Renewable Portfolio Standards (RPSs) requiring that a certain share of the electricity sold by utilities be generated from renewable energy resources; another three states and one territory have “renewable energy goals.”⁵⁵ In these jurisdictions, the production of renewable power generates RECs that utilities can buy to satisfy their obligations to deliver renewable energy to the grid. The ability to sell RECs thus acts as a financial incentive to producers of renewable energy, such as solar developers, because these producers can profit from selling RECs in addition to electricity.

In addition to promoting the addition of renewable sources to the grid to reduce GHG emissions, RECs also may help to lower electricity prices insofar as RECs increase the number of electricity suppliers. The ability of individual households to generate environmental attributes that they can sell, such as SRECs by installing solar panels, also may promote democratization of the

power sector by enabling individuals to participate in producing energy resources.⁵⁶

Despite the efficiency benefits of market-based environmental policies, the commoditization of environmental attributes has also raised a number of concerns from other perspectives. In particular, cap-and-trade programs have been the subject of a number of critiques.

From the perspective of moral philosophy, pollution markets have been criticized on the basis that it is immoral to allow countries or individuals to buy and sell the right to pollute. Permitting individuals to commoditize and trade in the right to cause environmental harm, it is argued, effectively removes the moral stigma associated with pollution and undermines the environmental ethic that society should be trying to foster.⁵⁷ The moral rebuke of emissions markets stems in part from the fact that these markets traditionally are centered around a distinct kind of environmental attribute—one that, by definition, harms the environment. Carbon allowances in California and in RGGI states, for example, permit their holders to emit carbon dioxide and other GHGs into the atmosphere, contributing to climate change. Similarly, allowances auctioned and traded under the federal Clean Air Act permit their holders to emit sulphur dioxide, a major contributor to acid rain.

However, not all environmental attributes damage the environment. Indeed, probably the most novel environmental resources are those that represent *avoided* consumption, rather than *active* consumption of environmental resources. For example, ESCerts or white certificates represent benefits to the environment, insofar as they are generated by measures that reduce the demand for electricity from fossil fuel fired power plants. RECs represent the environmental benefits of producing power from renewable, rather than fossil fuel, sources.⁵⁸ Even in the case of carbon markets, some jurisdictions have in recent years adopted a variation of the traditional carbon trading program which is centered on “credits” rather than “allowances.” In Tokyo’s cap-and-trade program, for example, salable credits are issued to facilities for verified, actual emissions reductions that go below a facility’s regulatory cap, only after which those attributes may be sold on the market.⁵⁹ Rather than “allowing” a facility to emit, facilities are instead given “credit” for emissions reductions that exceed

GOV’T, TOKYO CAP-AND-TRADE PROGRAM FOR LARGE FACILITIES (May 2015), https://www.kankyo.metro.tokyo.lg.jp/en/climate/cap_and_trade/index.files/TokyoCaT_detailed_documents.pdf [https://perma.cc/8CLD-9PZA].

what is required by regulation. From a moral perspective, compliance schemes centered around marketable “beneficial” attributes reward those that create environmental goods and penalize those that cause excess harm by requiring them to purchase others’ credits to make up for compliance shortfalls.

A second critique of market-based approaches to reducing pollution is that they have not been effective at addressing the environmental problems they seek to remedy. This critique suggests that certain environmental objectives, such as reducing GHG emissions, might be better achieved through traditional forms of regulation that require polluters to reduce their emissions onsite or through industrial policy.⁶⁰ For example, several carbon trading programs (including those in California and the European Union) have been criticized for not meaningfully reducing GHG emissions, particularly in the programs’ early years.⁶¹ Some argue that the failure of these programs to drive down GHG emissions (at least early on) may actually be due to emissions caps being set too low to incentivize action.⁶² Also, other complementary policies might have actually driven action at such a low cost that firms did not need to rely on trading to meet their compliance obligations.⁶³ Thus, the failure of some trading programs to achieve their environmental objectives might be explained by regulators’ design choices, rather than the choice of mechanism.

Perhaps the most pressing contemporary criticism of the commoditization of environmental attributes concerns the distribution of resulting benefits and harms. In other words, who wins and who loses when environmental attributes are propertized? Environmental justice groups have challenged recent efforts to develop cap-and-trade programs on the basis that they could allow polluters in low-income communities and communities of color to meet their obligations by purchasing credits from elsewhere instead of reducing emissions onsite, thereby generating pollution hot spots in disadvantaged communities.⁶⁴ However, the

64. For example, environmental justice groups have criticized California’s GHG cap-and-trade program as harming low-income communities and communities of color. Nathanael Johnson, *Cap and Trade-Offs: Did California’s Landmark Legislation Help or Hurt the State’s Most Vulnerable?*, GRIST (Oct. 19, 2020), <https://grist.org/climate/the-biggest-fight-over-cap-and-trade-isnt-about-what-you-think-it-is> [<https://perma.cc/82QJ-JG9K>]. Advocates have pointed to a study of the California program that found that in the first three years of the trading program, localized GHG emissions increased in disadvantaged neighborhoods. Lara J. Cushing, Madeline Wander, Rachel Morello-Frosch, Manuel

government always retains the authority to regulate to address distributional concerns to protect vulnerable communities.⁶⁵ Indeed, some governments have sought to do so. For example, new legislation in Washington State establishing a cap-and-trade program to reduce GHGs includes specific design elements to further environmental justice.⁶⁶ That being said, in the absence of concerted efforts to center environmental justice in designing and implementing programs, concerns likely will remain about whether markets for environmental attributes will inequitably reallocate environmental benefits and harms, and disadvantage environmental justice communities.⁶⁷

II. Initial Allocation of Ownership

Well-designed markets for environmental attributes may be socially beneficial. However, for markets to emerge, property rights in such attributes need to be initially allocated so that they can be sold.⁶⁸ Careful attention must be paid to the initial allocation of rights in novel resources, such as environmental attributes, because it is not always intuitive who owns these newly measurable resources and is therefore in a position to sell them.⁶⁹

But how does something that has never been owned, such as, returning to our introductory example, the avoided electricity use from the energy-efficient refrigerators, come to be owned for the first time? We posit that there are two key steps in the emergence of ownership: First, the resource must be assigned to a unique owner based on a principle such as first-in-time, accession, the highest

Paston, Allen Zhu & James Sadd, *A Preliminary Environmental Equity Assessment of California's Cap-and-Trade Program*, UNIV. OF CAL. BERKELEY (2016), <https://dornsife.usc.edu/PERE/enviro-equity-CA-cap-trade> [<https://perma.cc/H52N-9KSN>]; Lara Cushing, Dan Blaustein-Rejto, Madeline Wander, Manuel Pastor, James Sadd, Allen Zhu & Rachel Morello-Frosch, *Carbon Trading, Co-pollutants, and Environmental Equity: Evidence from California's Cap-and-Trade Program (2011-2015)*, PLOS MEDICINE (July 10, 2018). However, there are subsequent studies that find no adverse impacts on disadvantaged communities. Danae Hernandez-Cortes & Kyle C. Meng, *Do Environmental Markets Cause Environmental Injustice?* (Nat'l Bureau of Econ. Rsch., Working Paper No. 27205, 2021), <https://www.nber.org/papers/w27205> [<https://perma.cc/FG8D-WHY6>]; Kyle C. Meng, *Is Cap-and-Trade Causing More Greenhouse Gas Emissions in Disadvantaged Communities?*, in *DISTRIBUTIONAL EFFECTS OF ENVIRONMENTAL MARKET DESIGN: INSIGHTS AND SOLUTIONS FROM ECONOMICS 27-32* (C. Costello ed., 2018); Ryan Walch, *The Effect of California's Carbon Cap and Trade Program on Co-pollutants and Environmental Justice: Evidence from the Electricity Sector* (Nov. 1, 2018) (on file with authors).

65. See generally Daniel A. Farber, *Pollution Markets and Social Equity: Analyzing the Fairness of Cap and Trade*, 39 *ECOLOGICAL L.Q.* 1 (2012).

66. Brown, *supra* note 8.

67. For example, might the commoditization of water savings attributes lead to reduced efforts to conserve water resources in certain drought-prone regions if offenders can simply purchase offsets created in other regions?

68. Notably, we are not suggesting that the allocation of property rights is sufficient to generate markets. There also must be demand for a resource for there to be a market. Indeed, demand for the resource also may trigger the creation of property rights in the resource. See Demsetz, *supra* note 22.

69. To reiterate what was stated in the introduction, this Article does not argue that property rights and markets *should* be created in environmental attributes simply because the attributes can be isolated. Indeed, there may be instances in which society determines that property rights and markets are not appropriate, such as where other negative social consequences outweigh the environmental benefits that markets might provide. Also, if there is no demand to buy an attribute, there is no need to initially allocate property rights in it, or establish a market for it.

bidder, or labor.⁷⁰ The New York Supreme Court took this first step in the famous case of *Pierson v. Post* when it declared that Pierson owned the fox that he killed, not Post, because Pierson was the first to possess the fox.⁷¹ Second, the choice of a unique owner must come to bind the community at large so that owners such as Pierson have an *in rem* right that is good against the world, not merely an *in personam* right to an object that is good only against another individual, such as Post.⁷² With a right that is good against the world, a property owner has a “bundle of sticks,” whose content varies, but typically includes the right to sell the resource.⁷³ Contemporary property theorists usually think of others—such as the people on Long Island, where Pierson and Post lived—coming to be bound by an allocation as a result of top-down government decision embodied in legislation or regulation. Some also recognize the potential for an allocation to be ratified within society, without state involvement, through the emergence of a societal norm affirming the allocation.⁷⁴ In a distinct contribution, we highlight the potential for an allocation to come to be accepted through a combination of private and government action, drawing on our review of how some novel environmental attributes have recently been packaged into property.⁷⁵

This Part begins by explaining why, as a matter of law and economics, property rights need to be initially allocated in environmental attributes if society wishes to encourage their market exchange. Then, it identifies various *principles* that governments, private actors, and the courts, in the case of disputes, have used to identify unique owners of a novel environmental attribute. Finally, it discusses different *techniques* that have been used to bind the community at large to the choice of the unique owner of an environmental attribute.

A. The Need to Initially Allocate Rights

There are at least two reasons why, in order to stimulate markets, it is important to initially allocate property rights. First, as a legal matter, it is a basic

70. See also Thomas W. Merrill, *Accession and Original Ownership*, 1 J. LEGAL ANALYSIS 459, 474 (2009) (referring to first possession and accession as “operat[ing] . . . to identify unique persons as owners of particular resources”).

71. *Pierson v. Post*, 3 Cai. R. 175 (N.Y. Sup. Ct. 1805).

72. THOMAS W. MERRILL & HENRY E. SMITH, PROPERTY: PRINCIPLES AND POLICIES 19-20 (3d ed. 2017) (distinguishing *in rem* and *in personam* rights, and identifying property as an *in rem* right and contract as creating *in personam* rights).

73. The precise content of the owner’s bundle varies depending on many factors, including the nature of the resource and the time and place. In addition, modern property rights are often subject to many regulatory restrictions.

74. Many scholars distinguish between top-down and bottom-up explanations for how property rights emerge. See, e.g., STUART BANNER, WHO OWNS THE SKY 243-47 (2008); Richard A. Epstein, *The Allocation of the Commons: Parking on the Public Roads*, 31 J. LEGAL STUD. 515-44 (2002).

75. While we divide the creation of private rights into two steps for analytical purposes, the creation could be, and often is, discussed as a one-step process. When considered as a single step, the resource is allocated to one actor and that allocation is simultaneously assumed to bind the world. See, e.g., Richard A. Epstein, *Possession as the Root of Title*, 13 GA. L. REV. 1221, 1228 (1979). An issue in the creation of a property right that we do not discuss is the delineation of the scope of the right; we set to the side this important issue in this Article because we are concerned with how to allocate environmental attributes that we assume technology allows to be measured.

principle of property law that one cannot transfer what one does not own.⁷⁶ This principle is known as *nemo dat quod non habet*, meaning “one cannot give that which one does not have.”⁷⁷ While there are exceptions to this principle, it is the “baseline” in “all [legal] systems.”⁷⁸ Once there is an initial owner with title, that owner can then contract with others to sell the resource. The requirement to own energy efficiently to sell it in electricity markets instantiates the *nemo dat* principle.

Second, as a matter of economics, initially allocating property rights is likely to increase interest in selling and buying resources. As Coase explained, “[o]ne of the purposes of the legal system is to establish that clear delimitation of rights on the basis of which the transfer and recombination of rights can take place through the market.”⁷⁹ Private actors are less likely to buy assets that they are not certain that they will own upon purchase because the prior seller’s claim is uncertain. If private actors are willing to buy the resource notwithstanding the lack of the clarity about the seller’s title, buyers are likely to insist on a discounted price. In the face of diminished demand for the resource (and therefore lower prices), the incentive to supply the resource is reduced, and actors will limit the investments that they make in creating or capturing the resource. Thus, initially allocating property rights in resources may increase the demand for, and supply of, a resource and stimulate markets for it.

Property rights have been initially established in a number of environmental attributes, including GHG emissions (in allowances issued in the California and RGGI cap-and-trade programs), avoided GHG emissions (through offset credits created by private actors), the generation of renewable power (in RECs in various states and territories),⁸⁰ and avoided electricity use in white certificates and ESCerts (in France and Italy).⁸¹ However, as this list illustrates, the allocation of property rights in even these well-established environmental attributes remains incomplete, with many jurisdictions not having allocated rights in them.

76. MERRILL & SMITH, *supra* note 72, at 882-83 (discussing the *nemo dat quod non habet* principle).

77. *Id.* at 882.

78. Henry E. Smith, *On the Economy of Concepts in Property*, 160 U. PA. L. REV. 2097, 2120-23 (2012). Legal responses to the classic conundrum of whether a good faith purchaser can acquire title from a thief provide evidence of the existence of the *nemo dat* principle. Suppose a thief steals a car and then sells it to a car dealer who sells it to an innocent buyer; or the car thief sells the car directly to a buyer without knowledge of the theft. There are many different responses to the question of whether the car belongs to the buyer or to the original owner. Professor Yun-Chien Chang, who has assembled data on how 247 jurisdictions deal with the good faith purchaser problem, states that “American common law adopts the *nemo dat* doctrine—which basically kills the good-faith purchase doctrine—and the Uniform Commercial Code stipulates only two exceptions: the voidable title rule and the entrustment rule.” Yun-Chien Chang, *247 Jurisdictions in the World Get the Good-Faith Purchase Problem Wrong: A New Economic Framework* 14 (N.Y.U. Sch. of L., Working Paper No. 19-25, 2019). While emphasizing that *nemo dat* is the baseline legal principle, Smith underscores the exceptions that apply under certain circumstances involving land and personal property. Smith, *supra*.

80. *See supra* note 13.

81. *See infra* notes 173-174.

In addition, there are likely many other environmental attributes that have not yet been propertized, but which could be in the future as technology evolves to enable their measurement and demand emerges for them.⁸² For example, more efficient dishwashers avoid not only electricity use and GHG emissions, but also water use. The water savings likely could be quantified and sold if there were demand for them due to water scarcity in an era of climate change. When cows burp, they emit large amounts of methane, a potent GHG that is an important contributor to climate change. The methane emissions of cow herds can now be quantified, creating the potential to allocate ownership of allowances for methane emissions from cattle.⁸³ The idea of allocating ownership of water savings from dishwashers and cow methane emissions to facilitate their sale might sound fanciful, but it would have been unimaginable a hundred years ago that people would be selling allowances authorizing the release of carbon emissions.

New technology also may enable new players to claim rights to own environmental attributes, raising questions about whether to revise the rules for allocating attributes that are already packaged into property. For example, the proliferation of products equipped with smart and other internet-connected technologies enables households to measure and control their energy and water use remotely.⁸⁴ Households could potentially contract with companies to remotely measure and dispatch smart appliances and systems—if the households are recognized as the owners of the attributes that the new technology allows to be measured and dispatched.

Drawing on approaches that have been used to establish property rights in environmental attributes that are already traded, the next Section of this Article identifies a menu of principles and techniques for establishing property rights in

82. See generally Pappas & Flatt, *supra* note 53, at 771-72 (noting that technological changes may reduce the cost of severing resources and facilitate the development of markets in new resources).

83. Michael Allen, *Battling Bovine Belching: Measuring Methane Emissions from Cows*, 34 PHYSICS WORLD (Apr. 2021), <https://physicsworld.com/a/battling-bovine-belching-measuring-methane-emissions-from-cows> [<https://perma.cc/A848-N3B8>]. As an alternative to creating property rights in actual cow methane emissions, rights might be established in avoided cow methane emissions. For example, if the diets of cows were changed to reduce their burping and the avoided emissions could be quantified, private actors might be able to create credits in the attribute of avoided cow methane emissions that could be privately sold.

84. These products include smart temperature control in home thermostats and air conditioning units, automated lighting and window treatments, smart irrigation and security systems, and smart power outlets. Lucas Bergman, *Six Things to Know About Using Sustainable Smart Technology*, BIOFRIENDLY PLANET (Dec. 27, 2019), <https://biofriendlyplanet.com/green-alternatives/sustainable/6-things-to-know-about-using-sustainable-smart-technology> [<https://perma.cc/46P6-2BT2>]. Smart meters, which record and transmit information about energy consumption in real-time to consumers and utilities through a wireless network, are prominent examples of the potential of internet-connected technologies to transform the energy system. As of 2017, half of all electricity customers in the United States had smart meters. Miriam Aczel, *Measuring Up: Smart Meter Lessons from the United Kingdom*, ENV'T L. INST. (Feb. 12, 2018), <https://www.eli.org/vibrant-environment-blog/measuring-smart-meter-lessons-united-kingdom> [<https://perma.cc/9E9Z-9NXA>]. See also *Do Smart Meters Help the Environment?*, SMART ENERGY CONSUMER COLLABORATIVE, <https://www.whatissmartenergy.org/faqs/do-smart-meters-help-the-environment> [<https://perma.cc/M5AP-YUAB>]; *Energy Efficiency and Digitalisation*, INT'L ENERGY AGENCY (June 20, 2019), <https://www.iea.org/articles/energy-efficiency-and-digitalisation> [<https://perma.cc/S4BN-DAV4>].

currently unpropertized attributes. The principles and techniques outlined here may assist policymakers and private actors seeking to facilitate the marketability of environmental attributes, and may help judges and other adjudicators resolve ownership disputes.

B. Principles and Techniques for Allocating Ownership

We now analyze four principles that might be used to identify a unique owner of a novel resource: first-in-time, accession, the highest bidder in an auction, and labor. Then we discuss three possible techniques for persuading (or requiring) society to respect the initial ownership of the resource: top-down, bottom-up and hybrid approaches combining governmental and private actors.

The principles and techniques for initially allocating property rights identified below might be thought of as approaches that legislatures, regulators, courts, and private actors have considered means of promoting efficiency, distributive justice, and other goals.⁸⁵ The principles and techniques best suited to initially allocating a particular resource will likely vary depending on the characteristics of the resource, the state of technology, the policymaker’s goals for the resource, and other factors. The optimal approach for initially allocating rights to the same resource also might change over time, as understandings of the resource, the state of technology, and policy goals evolve.⁸⁶

A word about the potential to mix and match principles and techniques. In theory, any of the principles discussed below for identifying a unique owner of a novel environmental attribute might be coupled with any of the techniques for binding third parties to that allocation. However, some pairings of principles and techniques might be more effective than others in creating property rights. For example, if private actors are seeking to bind strangers to a particular allocation without the assistance of the government, it may be easier to use a principle that is intuitively easy to understand, such as a first-in-time rule like first possession. It may be easy for people generally—not only the hunters such as Pierson and Post, but also the other people living on Long Island—to accept that a resource is owned by the person who first possesses it, and respect that claim. Conversely, when more complex, less intuitive, principles are used to allocate a resource, such as investment in capturing it, then a technique such as regulation, which

85. See generally Guido Calabresi & A. Douglas Melamed, *Property Rules, Liability Rules, and Inalienability: One View of the Cathedral*, 85 HARV. L. REV. 1089, 1093 (1972) (discussing “economic efficiency, distributional preferences, and other justice considerations” as three broad categories of reasons for allocating entitlements). There could be other goals motivating the establishment of rights depending on the context. For example, as discussed in Part IV, policymakers might seek to create or recognize rights to energy resources to promote reliable and resilient access to energy.

86. See, e.g., Merrill, *supra* note 70, at 487 n.21 (referring to the evolution in approaches for allocating broadcast frequencies) (citing Thomas W. Hazlett, *Assigning Property Rights to Radio Spectrum Users: Why Did FCC License Auctions Take 67 Years?*, 41 J.L. & ECON. 529 (1998)); Troy A. Rule, *Property Rights and Modern Energy*, 20 GEO. MASON L. REV. 803 (2013) (discussing the evolution of property law in response to technological innovations in energy).

provides people with transparent notice of who the initial owner is, may be advantageous in binding strangers.⁸⁷

1. Step One: Principles for Identifying a Unique Initial Owner

We begin with the situation where it becomes technologically feasible to isolate a new environmental attribute that is currently unowned. For example, as mentioned in Section II.A, it is now feasible to measure the methane emissions from cattle, and these emissions are a significant source of methane. Suppose these emissions become valuable because governments decide to cap societal emissions of methane, and private actors want to sell and buy the right to emit. Several parties might claim to initially own the emissions, and have the right to sell them: the farmers who currently own the cows, the farmers who bred the cows, or the actors who figure out how to measure and bundle the emissions. How should private parties (or policymakers) determine who initially owns the cows' methane emissions?

We analyze four principles that have been used to identify an original owner for environmental attributes that have already been allocated:⁸⁸ a first-in-time principle under which the first party to do something is the initial owner; the principle of accession, under which ownership is assigned to the owner of some other pre-existing resource to which the new resource is proximately connected; the highest bidder principle, under which initial ownership is allocated to the party that offers to pay the most for the resource in a competitive auction; and labor, under which initial ownership is assigned based on labor or investment in the resource.

a. First-in-Time

One option is to award the methane emissions to the first party to measure the methane emissions consistent with the measurement and verification protocols established by the actors interested in buying the emissions. The law pervasively recognizes the first actor to do something with an unowned resource as the initial owner of that resource.⁸⁹ Historically, the first person to possess

87. See generally Henry E. Smith, *The Language of Property: Form, Context and Audience*, 55 STAN. L. REV. 1105 (2003) (emphasizing the implications of the costs of communicating information for the design of property law).

88. There are many other principles—or combinations of principles—that might be used to choose a unique owner, including need or random selection through a lottery. See Hazlett, *supra* note 86, at 533 (describing different methods of allocating licenses); Matthew Haag, *25 Million Applications: The Scramble for N.Y.C. Affordable Housing*, N.Y. TIMES (June 15, 2020), <https://www.nytimes.com/2020/06/15/nyregion/nyc-affordable-housing-lottery.html> [<https://perma.cc/8874-SGT6>] (describing an affordable housing lottery); Julie Satow, *Better Than the Powerball*, N.Y. TIMES (Jan. 11, 2019), <https://www.nytimes.com/2019/01/11/realestate/better-than-the-powerball.html> [<https://perma.cc/RN6M-XNS3>] (describing an affordable housing lottery).

89. Epstein, *supra* note 75, at 1221. For an accessible discussion of the benefits of using first-in-time to allocate initial ownership, see MICHAEL HELLER & JAMES SALZMAN, *MINE!* 24–30 (2021).

tangible things such as wild animals,⁹⁰ water (in the U.S. states that apply the rule of prior appropriation),⁹¹ and onshore oil and gas⁹² have been deemed the initial owner of these resources. Variations of the first-in-time principle are used to allocate initial ownership of intangibles. The first to file a patent application with the Patent and Trademark Office obtains the patent,⁹³ and first-in-time is used to initially allocate trademarks⁹⁴ and security interests.⁹⁵ Some emissions trading programs, such as the federal Acid Rain Program, initially allocate permits using prior appropriation, which is a variation of a first-in-time rule; the Acid Rain Program gave allowances to emit sulfur dioxide to electric utilities that were emitting sulfur dioxide prior to the passage of the program.⁹⁶

First-in-time is an attractive rule for choosing “a unique owner”⁹⁷ if the societal goal is to encourage private actors to capture an existing resource or create a new technology. It sets up a race, with the private actor who wins the race allocated a property right as a prize. It encourages people to race to secure the resource as quickly as possible because it provides people with property rights only if they are the first to possess or create the resource. It also encourages investment in technology to better capture the resource, and thus spurs innovation.⁹⁸ Using a first-in-time rule also makes it theoretically possible for anyone to secure the property right and thus encourages actors with no prior connection to the resource to enter the race, which also may promote

PUB. & INT'L L.* 55 (2003). By allocating allowances to utilities that had emitted sulphur dioxide in the 1980s, before the program was legislated, the program's designers avoided creating an incentive for utilities to emit sulphur dioxide in order to acquire free allowances.

97. Merrill, *supra* note 70.

98. *Id.*

innovation.⁹⁹ Unlike some of the principles discussed below, such as accession, it does not expressly favor incumbents, although in practice more financial means may help a party win the race.¹⁰⁰ Another attraction of first-in-time is that it should be straightforward to apply,¹⁰¹ at least after there is a clear definition of what must be done first to win the race.

In defining the actions that must be taken by a private actor to win the race, it makes sense to have in view the policy reasons for the race. In other words, to win the prize of the initial property right, a private actor should be helping to achieve the policy goals justifying the existence of the race. For example, in the nineteenth century, to acquire a prior appropriation water right in western U.S. states, private actors had to physically divert the water.¹⁰² Requiring diversion furthered the goals of promoting economic development by European settlers. However, in more recent decades, as the environmental objective of conserving water in a water system has gained currency, physical diversion of water is no longer required in all states to acquire—or maintain—a prior appropriation water right; in some states, water rights can be acquired or maintained based on leaving water in the stream.¹⁰³ This illustrates that as policy goals evolve, the actions required to win the race also may change.

In defining what must be done to win the race, it is also useful to define the end point so that it can be reached quickly. A definition that shortens the timespan of the race may reduce wasteful racing behavior.¹⁰⁴ As economist Dean Lueck argues, private parties likely will have different costs to capture the prize. If the race ends early, the party with lower costs likely will prevail before others spend resources to acquire the technology or skills that lowered the first party's costs.¹⁰⁵ Thus, the overall costs of obtaining the prize should be reduced from a societal perspective by keeping the race as short as possible.¹⁰⁶

Relatedly, what needs to be done to win the race should also be defined in a way that is intelligible to other participants in the race so that they will know the prize has been won and not waste their energies continuing to race for the same resource. Scholars such as Carol Rose emphasize that first possession

requires “a kind of communication,”¹⁰⁷ a “statement,”¹⁰⁸ or “notice”¹⁰⁹ that is intelligible to the relevant audience to “facilitate trade and minimize resource-wasting conflict.”¹¹⁰

Notwithstanding its many advantages, first-in-time is not an attractive rule in all circumstances. It may induce wasteful racing behavior to capture a resource,¹¹¹ particularly if there is not a clear definition of what it takes to win the resource that enables a quick resolution of the race.¹¹² First-in-time may also lead to over-consumption or premature consumption of a resource, as parties race to capture it before others, even if it would be preferable from a societal perspective to delay capture until the resource is more valuable.¹¹³ The risk of over-consumption is particularly problematic if the resource is finite, or renewable only over a long period of time. For example, for hundreds of years, ocean fisheries were allocated under a rule of first possession, with fishers acquiring property rights in the fish only after they had captured them. In the latter half of the twentieth century, incentivized by the rule of first possession, fishers invested in new aggressive capture technologies and used them to overfish ocean fisheries around the world.¹¹⁴ Countries have gradually responded by limiting the quantity of fish that fishers can catch, and awarding fishers permits to catch a share of the allowable catch. By providing fishers with a property interest in the stock of the fishery before they capture individual fish, these “catch shares” diminish the need for fishers to invest in boats and fishing gear to be the first to capture the fish, because fishers now have property rights to a share of the fishery before they remove the fish from the ocean. In effect, catch shares are a property-based approach for addressing the harms caused by allocating fish to the first party to catch them.¹¹⁵

As mentioned above, although a first-in-time rule does not in theory favor any particular party, it may in practice favor actors who have more resources to

115. *Id.*; Lueck, *supra* note 91, at 410.

invest in winning the race for the resource. The first-in-time rule of prior appropriation was adopted in Colorado in the nineteenth century to allocate water partly to prevent people from monopolizing the state's water by buying up land and securing water through landownership, as might have occurred if the riparian regime used in the eastern United States had been retained.¹¹⁶ However, the adoption of prior appropriation gave rise to the potential for “outside capitalists . . . to gain control of the region's waters by laying claim to the water diverted by the corporations they formed.”¹¹⁷ To ensure that water continued to be allocated in what was perceived as a distributively-just manner—and not concentrated in the hands of “investor-owned companies”—Colorado further adopted the rule that water rights “could be acquired only by actual [water] users.”¹¹⁸ As suggested by the history of Colorado water law, concerns that a first-in-time rule will favor parties with more resources can be addressed by attempting to craft a definition of what it means to “win” the race that leaves it open to many parties. Another option is subsidizing parties with fewer resources to enable them to better compete in the race.

b. Accession

A first-in-time rule allocates property rights to the party whose actions enable them to win a race. Accession is a competing principle that allocates initial ownership based on the “status” of already owning something else.¹¹⁹ According to Thomas Merrill, its best-known contemporary exponent, accession works by initially allocating property to a “newly discovered or newly salient resource . . . to the person who owns as property some other resource prominently connected with the newly discovered or salient thing. The factors that establish prominent connection, in a fashion analogous to those that establish first possession, also vary according to social context.”¹²⁰

Accession is sometimes used to establish property rights in environmental attributes. Landowners routinely believe that they own the right to extract energy from the wind blowing over their land based on their underlying landownership. Wind farm developers lease land to secure access to the energy from the wind, assuming that the landowners own the right to extract the energy.¹²¹ If cows' methane emissions became valuable, the owners of the cows might claim to own the cows' emissions on the basis that the emissions are closely connected to the cows that the owners already own.

Accession is a useful principle for initially allocating ownership to resources when property rights are already pervasively allocated to resources, and so there are pre-existing rights on which to piggyback new rights.¹²² It also is useful when many people share an intuition that a newly discovered or valuable resource is closely connected to an existing resource that is already propertized, and so there are unlikely to be competing property owners arguing that their property is closely connected to a new resource.¹²³

Accession is also useful when the owner of the existing resource is likely to be well-positioned to use the newly discovered or valuable resource to advance societal goals.¹²⁴ This might be the case because it is easier to exploit the new resource if one controls the pre-existing property. For example, one reason for initially allocating to landowners the right to extract energy from the wind blowing over their land is that landowner involvement is currently necessary to exploit wind energy because wind turbines must be placed on land. The close connection between controlling the land and extracting wind energy may help to generate the intuition shared by landowners and wind farm developers that landowners own the right to extract wind energy.¹²⁵

However, accession also has clear downsides as a rule for initially allocating ownership. For one, it rewards existing property owners with rights in new resources for free, without them having done anything to find or create the resource, and thereby enables the “rich to get richer”¹²⁶ based merely on their existing riches. In doing so, accession may enable existing property owners to make it difficult for others to enter an industry, especially if the newcomers have to acquire a property right in the new resource from an existing owner who obtained it for free. A number of market-based environmental regulatory programs, such as the fisheries catch shares mentioned above, initially allocated tradable permits using a version of accession and have been criticized for favoring incumbents by enabling them to realize windfall gains.¹²⁷

122. Merrill, *supra* note 70.

123. *Id.* at 477, 488.

124. *Id.*

125. Lifshitz, *supra* note 121, at 547.

126. Merrill, *supra* note 70, at 499.

127. Specifically, fishery catch shares have often initially been allocated for free to fishers who had fished before a certain date, with the number of shares each incumbent fisher received tied to the quantity of fish that the incumbent caught before the target date. Thus, the fish that the fishers caught and owned before the target date is the basis for their permit allocation, meaning that their permits accede to their prior ownership of fish. Once the catch share programs are up and running, fishers who own permits can then lease or sell these permits to other fishers who must own these permits to catch fish, which means that people who want to become fishers must rent or buy permits from the incumbents, who in some fisheries are called sealords. *See* Schwartz, *supra* note 44. Early emissions trading programs, such as the federal Acid Rain Program from the 1990s, allocated permits to emit a certain quantity of pollution for free to incumbent actors. These programs have also been criticized as creating barriers to new entrants. Keohane et al., *supra* note 96. Some commentators describe grandfathering as operationalizing first possession, but as is implicit in the text above, we think that grandfathering is better regarded as a version of accession. Jonathan Remy Nash, *Allocation and Uncertainty: Strategic Responses to Environmental Grandfathering*, 36 *ECOLOGICAL* L.Q. 809, 816 (2009); Terry Anderson, Ragnar Arnason & Gary D. Libecap, *Efficiency Advantages of Grandfathering in Rights-Based Fisheries Management*, 3 *ANN. REV. OF RES. ECON.* 159-79 (2011).

Accession will also be complicated to implement if there is no widely shared intuition that a new resource is closely connected to a particular existing resource.¹²⁸ Were it to become feasible to sell the water saved from water-efficient dishwashers, dishwasher manufacturers, homeowners, and water utilities, among others, might all have a claim to own property closely connected to the water savings. Delays in resolving disputes between potential claimants might hinder markets in water savings. But even if there is a widely shared intuition dictating who initially owns the resource, awarding it to an existing owner of another resource may slow down the exploitation of the new resource. For example, suppose ownership of the water savings is awarded to the homeowner who owns the dishwasher on the basis that the savings flow with the ownership of the dishwasher. Buyers of water savings might only want to buy large quantities of savings to avoid having to deal with a multiplicity of parties. Individual homeowners might not have a sufficient quantity of water savings to meet the demands of the buyers; thus, entrepreneurs might emerge who try to assemble water savings in the quantities demanded by the would-be-buyers. However, depending on the state of technology, the assembly efforts of the entrepreneurs might be thwarted if they need to contract with hundreds or thousands of individual homeowners to meet a buyer's demand for a minimum amount of water savings. Indeed, there are historical examples where accession was abandoned as a principle for allocating rights to novel resources because of concerns that accession would create transaction costs that would block innovation. In the early twentieth century, the *ad coelum* rule, which historically awarded landowners the right to the airspace above their land, was revisited to prevent landowners from blocking the development of commercial aviation.¹²⁹

It might be intuitive to allocate cows' methane emissions to the owner of the cows. In a similar instantiation of the principle of accession, calves are routinely initially allocated to the owner of the mother cow under the doctrine of increase.¹³⁰ However, allocating emissions ownership based on ownership of the cow could be seen as providing an undeserved windfall to cow owners, who might have done nothing to develop the technology to measure and monitor the cow emissions.

c. The Highest Bidder

Economists and economically-oriented legal scholars often recommend government-run auctions to allocate initial ownership of new or newly valuable resources to the highest bidder.¹³¹ Government-sanctioned auctions are used to initially allocate a number of the environmental attributes that have been

128. Merrill, *supra* note 70, at 492.

129. BANNER, *supra* note 74, at 30, 69, 260, 292-93.

130. MERRILL & SMITH, *supra* note 72 at 132-33.

131. See, e.g., Lueck, *supra* note 91, at 403; Schwartz, *supra* note 44; Merrill, *supra* note 70, at 486-87. Coase famously argued that the federal government should auction off spectrum frequencies, which it started doing in 1994. See Coase, *supra* note 79; Hazlett, *supra* note 86, at 530.

propertized to date, including allowances to emit GHGs in the carbon trading programs in California, RGGI, and the European Union.¹³²

There are several reasons for initially allocating property rights in previously unallocated attributes to the highest bidders in an auction. Auctions ensure that property owners pay for the value that they acquire through their new property rights, something which, the principle of accession, for example, grants to property owners for free. The property holder stands to benefit from any increases in the value of the resource, and so arguably should pay for the right, especially if no investment is necessary by the property holder to find or create the resource.¹³³

Initially allocating environmental attributes that harm the environment, such as carbon dioxide emissions, through auctions also instantiates the “polluter pays” principle by requiring polluters to pay some of the costs of their pollution.¹³⁴ To limit their expenditures on permits, polluters are incentivized to reduce their emissions. Furthermore, the revenues that the government raises from auctions can be used for many purposes, including compensating those harmed by the pollution that occurs, subsidizing investments to reduce the pollution, reducing the government’s reliance on inefficient taxes to pay for other programs and services, reducing the deficit,¹³⁵ or refunding money to taxpayers.

However, there also are downsides to using auctions to allocate initial ownership. For example, auctions are unlikely to be optimal if the environmental attribute that will be propertized needs to be created or discovered. The requirement that one purchase a property right to own it may discourage the creation or the identification of new resources, which itself may be costly.¹³⁶ Such a requirement might function like a tax, which can discourage activity. As discussed above, patents, which are awarded to encourage novel inventions, are allocated using a first-in-time rule according to which the first party to file a qualifying patent application wins the patent; parties are not required to buy the right to an invention before they invent it.¹³⁷ Patent law’s reliance on first-in-time fits with the hypothesis that auctions are less desirable compared to first-in-time

132. *Emissions Trading in Practice: A Handbook on Design and Implementation*, WORLD BANK GRP. 101-02 (2021), <https://openknowledge.worldbank.org/bitstream/handle/10986/23874/ETP.pdf> [https://perma.cc/499A-55KV].

133. Coase argued for auctioning access to the electromagnetic spectrum partly because he saw the free issuance of licenses to radio and television stations as giving station owners a windfall, as their FCC licenses enhanced the value of their stations. Coase, *supra* note 79, at 22-23.

134. The government could establish a minimum bid price for permits reflecting the harm caused by each unit of pollution authorized by a permit, and so therefore ensure that polluters purchasing permits pay at least the value of the harm caused by their pollution.

135. Hazlett, *supra* note 86, at 568 (noting that Congress allowed the FCC to auction broadcast licenses partly to help reduce the federal deficit).

136. See Michael Abramowicz, *The Uneasy Case for Patent Races Over Auctions*, 60 STAN. L. REV. 803, 828 (2007) (contemplating government auctions of patents to drugs, in which successful bidders would acquire “an exclusive right to use any inventions subsequently developed falling within the scope of the patent right”).

137. Lueck, *supra* note 91, at 403; Abramowicz, *supra* note 136, at 835.

rules, which set in motion a race, “when important resources are yet to be discovered.”¹³⁸

Similar to accession, allocating initial ownership to the highest bidder runs the risk of favoring well-heeled incumbent property owners.¹³⁹ The likelihood that an auction will enable those with deeper pockets to initially capture resources may not matter if the parties interested in the resources are mainly wealthy entities. Moreover, if there is a desire to promote greater access to the resource, portions of it might be given away for free, or programs might be developed to assist less-resourced parties to participate in auctions. However, such programs would need to be funded.

Allocating property rights to the highest bidder through an auction also might entail higher administrative costs than using a first-in-time rule or accession.¹⁴⁰ The government would need to be able to precisely define the resource that it is auctioning,¹⁴¹ and to administer the auction or delegate auction administration to a third party. While the government might charge the parties acquiring property rights a fee that covers the cost of running the auction, the complexity of creating the rules governing the auction might discourage governmental use of auctions, especially when the resources being propertized are not valuable or not yet in existence.¹⁴² Were a government to auction rights to own cows’ methane emissions, the government would likely need to be able to delineate rights to the emissions of groups of cows, in a defined geography, over a defined period of time, accounting for uncertainty and differences among cows.

138. Lueck, *supra* note 91, at 410. *See also id.* at 471; Abramowicz, *supra* note 136, at 835. Between 1920-1926, the radio spectrum was claimed using first possession, a rule that commentators have argued was justified in this period when the spectrum was initially discovered. Lueck, *supra* note 91, at 419; Hazlett, *supra* note 86, at 543; THOMAS WINSLOW HAZLETT, *THE POLITICAL SPECTRUM: THE TUMULTUOUS LIBERATION OF WIRELESS TECHNOLOGY FROM HERBERT HOOVER TO THE SMARTPHONE* 38-46 (2017).

141. Abramowicz, *supra* note 136, at 829-30 (cautioning that the government might allocate excessively-broad property rights if precise definition is not possible).

142. *Id.* at 835 (“As Aditya Bamzai has pointed out, ‘[a]uctions are . . . less useful when government policy aims to induce private investment in the discovery of new goods, and more useful when the government has already identified the good in question.’ Bamzai cites intellectual property as an example of this general point, noting that ‘the auction method requires that the government know what it is auctioning off.’”) (citing Aditya Bamzai, Comment, *The Wasteful Duplication Thesis in Natural Monopoly Regulation*, 71 U. CHI. L. REV. 1525, 1546 (2004)).

d. Labor

John Locke famously argued that people acquire initial ownership of resources by laboring on them; a forager acquires the right to their acorns through picking, and thereby appropriating, them.¹⁴³

Closely related to the idea that ownership should be allocated based on labor is the idea that it should be awarded to the actor who creates the resource (or pays for the creation of the resource). Under this approach, creating the resource (or paying for its creation) generates the claim of ownership, rather than the physical act of laboring on the resource. Something like a “pay to create” principle has been used to allocate ownership of environmental attributes. When states first created RECs, public utility commissions and courts had to decide how to allocate ownership of these credits for renewable energy sold by power producers to utilities under long-term contracts that predated RECs. Decision-makers allocated ownership of the RECs to the utilities that bought the power, not the renewable power generators.¹⁴⁴ This can be seen as instantiating the principle of accession: the RECs were closely associated with the renewable power that the utilities were buying from the generators, and so it is logical that the RECs were deemed to flow with the power to the utilities. The fact that the utilities paid a premium for the renewable power that generated the RECs also seems to have helped the utilities, at least in one court. In upholding the decision of the New Jersey Board of Public Utilities to allocate the unassigned RECs to the utilities rather than the renewable power generators, a New Jersey court identified the fact that the utilities had paid above market price for the power to subsidize the spread of renewable power as a factor weighing in favor of the utilities’ claim to the RECs.¹⁴⁵

Allocating ownership to the person who labored to capture an existing resource or create a new one is often justified as a way of encouraging innovation.¹⁴⁶ It also satisfies a common moral intuition that people should be rewarded for their efforts. Rewarding effort may seem especially morally compelling when it produces something that benefits not only the laborer, but also society at large.

However, labor and the principles related to it will often provide an indeterminate basis for allocating initial ownership. It is necessary to define what counts as labor that will give rise to ownership, similar to the way it is necessary to define what acts count as winning the race to be first-in-time.¹⁴⁷ Is touching

143. JOHN LOCKE, THE SECOND TREATISE OF GOVERNMENT, *in* TWO TREATISES OF GOVERNMENT § 27 (Ian Shapiro ed., Yale Univ. Press 2003) (1690).

144. *In re* Ownership of Renewable Energy Certificates, 913 A.2d 825, 828 (N.J. Super. Ct. App. Div. 2007).

145. *Id.* at 830.

146. HELLER & SALZMAN, *supra* note 89, at 102.

147. *Id.* at 84 (“Labor—like *first-in-time* and *possession*—is not self-defining.”). Policy, ideology, and prejudice have influenced whose labor is considered sufficient to acquire property. *See, e.g.*, Park, *supra* note 112, at 33-34, 36-37 (discussing the disregard of the labor of Native Americans by Locke and colonists).

the apple enough, or must a person actually pick the apple to own it?¹⁴⁸ Another problem with trying to use labor to allocate initial ownership is that resources will often be captured, or come into being, due to the efforts of a number of actors. Value is often socially created; the actions of multiple people are often necessary to create or capture things. For example, the renewable energy attributes proptertized in RECs are the product of the efforts of the manufacturers that make the solar panels, the installers who put them on rooftops, the consumers who buy or lease them, and the companies that finance the production, sale, and installation of the panels. If initial ownership were to be allocated based on labor, then all of these parties should be assigned some share. But having multiple initial owners would complicate the use of the resource, as the consent of multiple parties would be necessary to govern and transfer it.

2. Step Two: Techniques for Binding “the World”

Assuming a newly identifiable resource, such as cow methane emissions or water savings from an efficient appliance, has been assigned to one of the actors with a plausible claim to it, how does that assignment come to bind strangers not a party to the initial assignment? There are three options: top-down with the state acting through law and backed up by force if necessary; bottom-up through the development of a societal norm or custom that people feel bound to respect; or through a hybrid of state and private actions.

Absent from this list of options is the potential to bind strangers to an initial allocation through contracts. Although small numbers of people can allocate resources among themselves through contracts, it would be too costly to negotiate the many contracts that would be necessary to secure an *in rem* right good against the world through contracting. Moreover, even if it were possible to negotiate a series of contracts in which everyone in the world agreed to an initial allocation, those contracts would need to be updated each time the resource was transferred to enable the new owner to similarly enjoy an *in rem* right good against the world.¹⁴⁹

a. Top-down Approaches

Modern property theorists usually assume that private property comes into being in a top-down fashion, with the state acting through legislation or

148. LOCKE, *supra* note 143. Robert Nozick famously asked rhetorically whether one could come to own the ocean by dumping a can of tomato juice into it. ROBERT NOZICK, ANARCHY, STATE AND UTOPIA 175 (1974).

149. The practical obstacles to establishing *in rem* property rights through contracts were recognized hundreds of years ago, and continue to be a theme in modern property theory. LOCKE, *supra* note 143; Matt Schrage, *Rousseau and Locke on Property and the State*, MATT SCHRAGE (BLOG) (Apr. 26, 2018, 4:39 PM), <https://blogs.harvard.edu/mattschrage/2018/04/26/rousseau-and-locke-on-property-and-the-state> [https://perma.cc/4EXV-NQZK]; BANNER, *supra* note 74, at 293; Rose, *supra* note 108, at 74 n.8; J.E. PENNER, PROPERTY RIGHTS: A RE-EXAMINATION 86 (2020) (arguing that property is not “an extensive web of one-to-one right-duty relations that links us with every other person”).

regulation.¹⁵⁰ Consistent with the standard view, many recently propertized environmental attributes were initially allocated in a top-down fashion by state actors, such as legislatures and administrative agencies. California’s GHG trading program was established by regulation by the California Air Resources Board (CARB) pursuant to the Global Warming Solutions Act of 2006.¹⁵¹ Under these regulations, CARB distributes GHG allowances—each of which authorizes the emission of a ton of GHGs—through a combination of auctions and free allocations.¹⁵² There are other types of environmental property rights that private actors create pursuant to statutorily authorized rules. To promote the sale of electric vehicles, California’s ZEV regulation requires vehicle manufacturers to have a certain percentage of their in-state sales be of zero-emission vehicles or to supply ZEV credits instead.¹⁵³ Car manufacturers generate these ZEV credits by manufacturing certain types of vehicles—such as electric cars—which they can then sell to other car manufacturers that have not met their ZEV targets.¹⁵⁴

RECs, which exist in over half of U.S. states, are another example of property rights created pursuant to legislation and regulation. Although the legal framework varies depending on the state, the standard practice at the state level seems to be to assign initial ownership of the REC by regulation to the generator of the renewable power, with the power generation providing the basis for the credit.¹⁵⁵ State law usually provides a mechanism for certifying the validity of the credit through a state certification agency. The generator is free to transfer the credit by contract to utilities or others who may use the credit to comply with regulatory requirements.

There are at least two reasons why environmental property rights such as the California GHG allowances, ZEV credits, and RECs have been created

150. Thomas W. Merrill & Henry E. Smith, *Optimal Standardization in the Law of Property: The Numerus Clausus Principle*, 110 YALE L.J. 1, 60 (2000) (novel property rights have usually been created by legislation in the United States). The idea that property rights are created from above by the state acting through law has a long lineage. *See generally* JEREMY BENTHAM, PRINCIPLES OF THE CIVIL CODE, CH. VIII: OF PROPERTY (Bowring ed., 1843), <https://oll.libertyfund.org/title/bowring-the-works-of-jeremy-bentham-vol-1> [<https://perma.cc/36AU-ZMF8>] (“Property and law are born and must die together. Before the laws, there was no property: take away the laws, all property ceases.”).

151. CAL. HEALTH & SAFETY CODE § 38562(b)(1), § 38570(a), § 38505(k) (West 2021); CAL. CODE REGS. tit. 17, § 95801 *et seq.* (2021).

152. *Allowance Allocation*, CAL. AIR RES. BD., <https://ww2.arb.ca.gov/our-work/programs/cap-and-trade-program/allowance-allocation> [<https://perma.cc/7SKC-LT4R>]; *see also* CAL. CODE REGS. tit. 17, § 95820(a) (2021) (authorizing creation of allowances); *id.* at § 95802 (defining “Allowance”).

153. CAL. CODE REGS. tit. 13, § 1962.2 (2021). For background on the ZEV regulation, and its adoption by other U.S. states, see Alexandra B. Klass, *Public Utilities and Transportation Electrification*, 104 IOWA L. REV. 545, 579-81 (2018).

154. The terms for generating ZEV credits are set by the California ZEV regulation promulgated under the authority of the state’s Health and Safety Code. Carmakers can also generate credits under federal law. Leard & McConnell, *supra* note 20.

155. *See, e.g.*, N.H. REV. STAT. ANN. § 362-A:9 (2021) (“Renewable energy credits shall remain the property of the customer-generator until such credits are sold or transferred. If an electric distribution utility acquires renewable energy credits from a customer-generator in conjunction with purchasing excess generation, it may apply such generation and credits to its renewable energy source default service option under RSA 374-F:3, V(f).”). Thus, the principle of accession seems to govern the initial allocation, with the credit being initially assigned to the party that generated the power.

pursuant to legislation. One is that these property rights were established by governments as part of policies to achieve environmental regulatory objectives (such as reducing GHG and local co-pollutant emissions or increasing demand for, and the supply of, renewable power). The entitlements these property rights provide (such as the right to emit GHGs) would not have value in the absence of the broad regulatory programs of which they are a part. Second, creating these rights pursuant to publicly-available legislation has the benefit of making it easier for third parties to learn of the rights and their limits, and therefore of reducing the cost of enlisting third parties to respect the rights.¹⁵⁶ Because the rights are defined by written legislation or regulation, the scope of the rights can be readily discerned by interested parties. The authoritative definition of the scope of the property rights in legislation or regulation is likely particularly valuable when the rights concern intangibles or other things that are not observable to the naked eye — such as the right to emit a ton of GHGs. Notably, property rights in other intangibles, such as copyrights and patents, also are established pursuant to legislation.

b. Bottom-up Approaches

Although there are advantages to creating new property rights through legislation and regulation, the state may be slow to act. Thus, private parties seeking to realize the value of a newly discovered resource may attempt to create private rights in the resource on their own, without appealing to state actors. An important question is how private parties can select a unique owner and get third parties to respect the rights of that owner without the involvement of the state.

Some scholars have elaborated theories about the conditions under which private actors can create property rights independent of the state. For example, Professor Robert Ellickson argues that “close-knit groups” of people can evolve efficient property rights.¹⁵⁷ Ellickson argues that small numbers of people who engage regularly with each other may be able to use informal techniques, such as gossip or shaming, to punish people who do not respect each other’s rights, and therefore encourage respect for those rights.¹⁵⁸ Ellickson describes

156. In suggesting that the delineation of environmental property rights in legislation and regulation lowers the costs for third parties to understand the rights, we draw on the work of Merrill and Smith arguing that legislatures are superior institutions to courts for establishing new forms of property rights. Merrill & Smith, *supra* note 150. They argue that legislation is more likely than court decisions to delineate new rights in a clear, comprehensive, and accessible format. *Id.* at 58-68 (identifying six reasons why legislative creation of new property rights reduces information costs for private third parties compared with judicial creation).

157. Robert C. Ellickson, *Property in Land*, 102 YALE L.J. 1315, 1320 (1993). Ellickson’s theory “is an application of” his general theory that close-knit groups evolve efficient social norms. *Id.* at 1320 n.15. Like top-down theories, bottom-up theories of how property rights emerge also have a long lineage. For example, David Hume argued that property emerges through an implicit convention, as people come to respect others’ holdings because doing so produces a “peace dividend.” See Jeremy Waldron, *To Bestow Stability Upon Possession’: Hume’s Alternative to Locke*, in PHILOSOPHICAL FOUNDATIONS OF PROPERTY LAW 1 (James Penner & Henry E. Smith eds., 2013).

158. See Ellickson, *supra* note 157, at 1320-21.

nineteenth-century whalers as a close-knit group that evolved norms which allocated ownership of whales in a manner that was efficient, at least for the whalers, if not for the whales (which the whalers overfished) and people outside the whaling community (whose interests the norms did not seek to promote).¹⁵⁹

A prominent contemporary example of private parties allocating rights to environmental attributes without the state is carbon offset credits that private parties create and sell to other private actors who are not required by government regulation to purchase such credits. As private companies and institutions are making voluntary pledges to reduce their own GHG emissions to address climate change, many are increasingly purchasing carbon credits from private markets to offset emissions they cannot reduce or eliminate on their own.¹⁶⁰ Recently, experts have estimated that the global demand for voluntary carbon credits could increase by a factor of fifteen in the next ten years, and a factor of one hundred in the next thirty.¹⁶¹

Growing voluntary markets also exist for renewable electricity, “driven by consumer preference for certain types of renewable energy” rather than state mandates; these markets are colloquially known as “green power markets.”¹⁶² In 2019, the attributes sold on these green power markets, which are distinct from mandatory markets for renewables used to meet state RPS requirements, constituted 164 million megawatt-hours of renewable energy, representing about four percent of U.S. retail electricity sales.¹⁶³ Voluntary markets for new environmental attributes could also arise even in the absence of a parallel regulatory market. For example, as many parts of the world face increasing water scarcity and drought, voluntary markets could help private actors meet commitments for water resource conservation.

The emergence of privately-created carbon credits appears to be an instance where nonstate actors have been able to set and enforce standards that are respected by third parties,¹⁶⁴ although there are questions about whether the

privately-created credits truly represent additional reductions in GHG emissions.¹⁶⁵ Verifiers and registries in carbon offset markets play an important role in the process of allocating ownership by cutting off rival claims to particular carbon offsets. In certifying the offset, the verifier signals to the market that ownership over the attribute created by a particular activity, in a particular geography, during a particular time, has been claimed.¹⁶⁶ By entering the attribute into a registry, the market notifies the public of that ownership.¹⁶⁷ In this sense, private parties have assumed the role of the state in allocating ownership of attributes. However, in the event of a dispute about who owns a set of avoided emissions, the competing claimants might go to the courts (a state agent) to settle who owns the resource. Underscoring the significance of private efforts, the courts might choose to apply rules initially developed by private actors.¹⁶⁸

c. Hybrid Approaches

While scholars tend to think of property rights emerging in either a top-down or a bottom-up fashion, our review of how some environmental attributes have been packaged into tradable instruments suggests the potential for a third possibility: property rights might emerge through a hybrid of bottom-up and top-down activity. After identifying a new resource, private actors might use contracts to claim rights to it from a small number of plausible competing claimants. To bind the world, the entrepreneurs who defined the resource and sought to claim it through contracts might then appeal to a legislature or administrative agency to ratify their property rights and cut off third party claims.¹⁶⁹

The process by which property rights are created in energy efficiency in France provides an intriguing example of rights emerging through a combination of bottom-up contracting and top-down state activity. Several European

166. The Verified Carbon Standard (VCS), “the world’s most widely used voluntary” carbon offset program, has certified almost 1,700 different projects. Under the VCS program, auditors assess projects against VCS rules. *Validation and Verification*, VERRA, <https://verra.org/project/vcs-program/validation-verification> [https://perma.cc/5UGA-4T8U].

167. VCS certified projects are transparently registered in the Verra registry. *Registry System*, VERRA, <https://verra.org/project/vcs-program/registry-system> [https://perma.cc/S7XX-NB5D].

168. There are precedents for courts using norms developed by private parties to allocate property rights. In the classic case of *Ghen v. Rich*, the court held that a third party was bound by the customary rules that whalers had developed for allocating whales. *Ghen v. Rich*, 8 F. 159 (D. Mass., 1881).

169. Although usually thought of as a bottom-up theory of how property emerges, Locke’s “labor theory” might actually be a hybrid theory. Locke suggests that people acquire property rights in unowned things by laboring on them (for example, by picking the apples), but he also envisages people entering into a social contract to form the state to protect their rights. LOCKE, *supra* note 143, at § 138; see also Waldron, *supra* note 151, at 2 (noting that in Locke’s theory, people “enter into society” to preserve their property). The state is the mechanism that secures people’s holdings, by ratifying and then protecting against incursions.

countries¹⁷⁰ and 22 U.S. states¹⁷¹ obligate energy companies, such as electrical and gas utilities, to increase energy efficiency for various reasons, including reducing GHG emissions and facilitating the reliability and security of electricity supply.¹⁷² In France and Italy, regulated parties can meet their obligations by supplying “white certificates,” which they can generate through programs to reduce energy consumption or purchase from other parties that have reduced energy consumption.¹⁷³ Five of the 22 U.S. states with mandatory energy efficiency resource standards also formally allow obligated entities to comply by trading ESCerts.¹⁷⁴

Multiple parties could have claims to the avoided energy use from an energy efficiency improvement. For example, if a boiler is replaced in an apartment building, the claimants might include: the manufacturer of the new, more energy-efficient boiler, the actor installing the new boiler, the lender financing the new boiler, the energy supplier that might have informed the building owner of the potential benefits of the project and incentivized it, and the building owner.¹⁷⁵ In France, “all parties in [a] position to claim the certificates” must agree in a contract about who will own the white certificate (which can be divided up among the parties).¹⁷⁶ “This contract is then submitted at the time when the certificates are actually claimed,” and certification is undertaken by a

173. REZESSY & BERTOLDI, *supra* note 170; see also Noah M. Sachs, *The Limits of Energy Efficiency Markets in Climate-Change Law*, 2016 U. ILL. L. REV. 2237, 2253 n.77 (suggesting that there is minimal trading in France, but more trading in Italy). For a discussion of the Italian white certificate program, see CATAPULT ENERGY SYS., ENERGY TECH. INST., RICARDO ENERGY & ENV’T, ITALIAN ENERGY EFFICIENCY WHITE CERTIFICATE SCHEME (2018), <https://esc-production-2021.s3.eu-west-2.amazonaws.com/2021/09/Italy-White-Certificate-Scheme-Case-Study-FINAL.pdf> [<https://perma.cc/SJ5D-FBTJ>] and D. DI SANTO & E. BIELE, EVALUATION INTO PRACTICE TO ACHIEVE TARGETS FOR ENERGY EFFICIENCY (EPATEE), THE ITALIAN WHITE CERTIFICATES SCHEME (2017), https://epatee.eu/sites/default/files/epatee_case_study_italy_white_certificates_ok.pdf [<https://perma.cc/7GTN-JA2A>].

174. The five are Connecticut, Massachusetts, Michigan, Nevada and Pennsylvania. Sachs, *supra* note 14, at 10469. However, there may not be any trading occurring in any of these states. In a 2016 article, Professor Sachs indicated that trading was actively occurring only in Connecticut. *Id.* While energy efficiency can be used to generate Class III credits under Connecticut’s Renewable Portfolio Standard, projects supported by ratepayers are no longer eligible to receive credits as of 2014, and energy efficiency is not currently being used to generate Class III credits. CONN. GEN. STAT. ANN. § 16-243q(a)-(c), § 16-1(38), § 16-243t(a) (2021). See also *Connecticut Renewable Portfolio Standard*, CONN. DEP’T OF ENERGY & ENV’T PROT., PUB. UTIL. REGUL. AUTH., <https://portal.ct.gov/PURA/RPS/Renewable-Portfolio-Standards-Overview> [<https://perma.cc/4PTM-W4BF>] (describing the Connecticut Renewable Portfolio Standard). Sachs opposed the development of ESCert markets, based partly on his critique of existing markets. Sachs, *supra* note 173.

175. The example is drawn from Bertoldi & Rezessy, *supra* note 14, at 20 n.25.

176. *Id.*

government agency in France.¹⁷⁷ In other words, the French regime for initially allocating white certificates involves bottom-up contracting among the plausible potential claimants to the energy efficiency to allocate ownership, and top-down certification that seems to implicitly approve the parties' contractual allocation.

There are at least two reasons why a hybrid approach for initially allocating property might be desirable under certain conditions. For one, private actors might be better positioned to initially define some resources and identify the most suitable unique owner than the legislature or a regulatory agency. Legislators or regulators might have difficulty establishing a universal rule about which party should be assigned the right to profit from the energy efficiency initiative. Who finances the energy efficiency measure, or who is best positioned to profit from the avoided electricity use, might vary greatly depending on the circumstances.

Second, the state might play a useful role in validating or confirming the private parties' initial definition of the resource and assignment of it to a unique party (or parties). Through the validation process, the state might confirm that the resource that the private parties are claiming has not already been claimed by other parties. If there is no public registry of the property rights that have already been claimed in the resource, the state validation process might be the mechanism for verifying that two or more parties are not claiming the same resource. If there is such a registry, the state validation process might be the means of ensuring that registry is kept up to date and that the rights are respected.

State validation of the parties' definition and allocation of the resource also might be the means by which the parties' arrangements come to bind strangers with whom they have not contracted, and who also might have a claim to the resource. As discussed above, it will not be practical for a party to establish an *in rem* right by literally contracting with all the parties who might claim the resource. For example, the tenants of the apartment building also might have a claim to the energy use avoided through the installation of the new boiler, as they may have contributed to the cost of the boiler through a rent increase. Yet it might be too costly to negotiate with the tenants to renounce their claims to the avoided energy consumption, especially if there are many tenants, they turn over frequently, and the value of the avoided consumption is small relative to the transaction costs of negotiating with the tenants. By lending its imprimatur to the parties' initial definition and assignment of the rights, the state validation process gives them the force of law and binds third parties to the assignment.

III. Application to Energy Efficiency Resources

This Part applies the menu of approaches for propertizing environmental attributes outlined in Part II to a question with which this article began: who initially owns the environmental attributes derived from energy efficiency initiatives? Already traded in some jurisdictions, energy efficiency is an attribute

177. *Id.* at 20; *see also id.* at 19; Sachs, *supra* note 14, at 10467.

that might be traded more if there were clearer legal rules for initially assigning ownership to it.

Energy efficiency involves reducing the energy required for a given activity. For example, switching from incandescent to LED bulbs reduces the electricity required to light a lamp by 75 to 80 percent.¹⁷⁸ Improving energy efficiency offers a number of benefits.¹⁷⁹ Insofar as electricity is generated from fossil fuels, reducing the electricity required to accomplish a task reduces the use of fossil fuels and the accompanying emissions of GHGs and co-pollutants harmful to human health, such as particulate matter. Improving energy efficiency also benefits the power system. Because there are still limits on the extent to which electricity can be stored, the supply of power must always match the demand for power. Energy efficiency improvements reduce demand for power, thereby reducing the need to expand generation, transmission, and distribution capacity.¹⁸⁰ Improving energy efficiency also lowers electricity bills for consumers, businesses, and governments because it lowers energy consumption.¹⁸¹

As a result of technological innovations over the last few decades, it is feasible to estimate and verify the energy use avoided through efficiency measures, such as switching to LED lightbulbs, installing energy-efficient appliances such as refrigerators and washing machines, and weatherizing buildings by sealing leaks.¹⁸² An important step in doing so is establishing a baseline of what energy use would have been absent the energy efficiency measures.¹⁸³ The proliferation of smart and internet-connected devices makes it increasingly possible to obtain reliable real-time data on consumer energy use,

178. *Energy Efficiency 101*, RES. FOR THE FUTURE (June 17, 2020), <https://www.rff.org/publications/explainers/energy-efficiency-101> [<https://perma.cc/25MZ-WVZX>].

179. See *Quantifying the Multiple Benefits of Energy Efficiency and Renewable Energy: A Guide for State and Local Governments, Part One: The Multiple Benefits of Energy Efficiency and Renewable Energy*, EPA (2018), https://www.epa.gov/sites/production/files/2018-07/documents/mbg_1_multiplebenefits.pdf [<https://perma.cc/WF6C-2Z6C>]; *Multiple Benefits of Energy Efficiency*, INT'L ENERGY AGENCY (2019), <https://www.iea.org/reports/multiple-benefits-of-energy-efficiency> [<https://perma.cc/L7MC-ZAUQ>].

180. *Multiple Benefits of Energy Efficiency: Air Quality*, INT'L ENERGY AGENCY (2019), <https://www.iea.org/reports/multiple-benefits-of-energy-efficiency/energy-prices> [<https://perma.cc/7EVQ-UTKY>]. Notably, some resources which are valuable for their environmental attributes might also be valuable for their energy attributes in certain markets, to the extent that the primary benefit sought by their commodification is to eliminate the need for additional energy supply. For example, as discussed below, energy efficiency resources are valued for their energy attributes in wholesale electricity markets.

181. *Multiple Benefits of Energy Efficiency: Air Quality*, INT'L ENERGY AGENCY (2019), <https://www.iea.org/reports/multiple-benefits-of-energy-efficiency/household-savings> [<https://perma.cc/3UFV-4KMR>].

182. *Energy Efficiency 101*, *supra* note 178. See, e.g., *PJM Manual 18B: Energy Efficiency Measurement and Verification, Revision: 04*, PJM FORWARD MARKET OPERATIONS (Aug. 22, 2019), <https://pjm.com/~media/documents/manuals/m18b.ashx> [<https://perma.cc/5298-9R2J>]; *Guidebook for Energy Efficiency Evaluation, Measurement and Verification*, EPA (June 2019), https://www.epa.gov/sites/default/files/2019-06/documents/guidebook_for_energy_efficiency_evaluation_measurement_verification.pdf [<https://perma.cc/NWM8-6FZR>].

183. *Guidebook for Energy Efficiency Evaluation, Measurement and Verification*, *supra* note 182, at 10.

which can improve the accuracy of estimation techniques and potentially reduce the need to rely on these techniques. All of this technological change means that avoided energy consumption from efficiency improvements and appliances can be isolated and transferred as a distinct and separate product.

Indeed, several types of markets for energy efficiency attributes already exist. As mentioned in Part II, electric and gas utilities in some jurisdictions are eligible to trade ESCerts denoting specific quantities of avoided energy use to comply with government requirements to improve energy efficiency.¹⁸⁴ Energy efficiency is also eligible to participate in some of the wholesale electricity markets that FERC oversees, in particular PJM Interconnection, L.L.C. (PJM),¹⁸⁵ the New England Independent System Operator (ISO-NE), and the Midcontinent Independent System Operator (MISO) capacity markets.¹⁸⁶ In capacity markets, utilities purchase electricity supply obligations to ensure that sufficient electricity will be available in the years ahead to reliably meet demand.¹⁸⁷ The amount of energy efficiency sold into wholesale markets has varied over time.¹⁸⁸ FERC Order 2222 could further increase the quantity of energy efficiency sold

184. Sachs, *supra* note 14, at 10469.

185. PJM is the Regional Transmission Organization for all or part of 13 states and the District of Columbia.

186. PJM, ISO-NE, and MISO have tariff provisions permitting energy efficiency resources to participate in wholesale electricity capacity markets. OATT Attachment DD-1.L [PJM]; OATT Market Rule 1, § III.13 [ISO-NE]; OATT § 69A.3.2 [MISO]; Kathleen Spees, Walter Graf & Johannes Pfeifenberger, *The Benefits of Energy Efficiency Participation in Capacity Markets*, BRATTLE GRP. (2021), <https://info.aee.net/hubfs/The%20Benefits%20of%20Energy%20Efficiency%20Participation%20in%20Capacity%20Markets1.pdf> [<https://perma.cc/2C3U-75R5>]. While most U.S. capacity markets allow energy efficiency to participate as supply-side resources, markets have experienced different rates of participation due to differences in market design and participation rules. Spees et al., *supra*, at 2.

187. See, e.g., Shelley Welton, *Rethinking Grid Governance for the Climate Change Era*, 109 CALIF. L. REV. 209, 231 (2021).

188. See Spees et al., *supra* note 186, at 3 (“Regardless of market differences, trends in [PJM, ISO-NE, and MISO] point to the growing penetration of [energy efficiency]. Cleared [energy efficiency] supply has increased by 170% in ISO-NE and by more than 300% in PJM in the last ten years. In MISO, it has increased from zero supply in the 2016-17 planning year to its present level.”); *State of the Market Report for PJM, MKT. ANALYTICS, LLC* 340 (2020), https://www.monitoringanalytics.com/reports/PJM_State_of_the_Market/2019/2019-som-pjm-sec7.pdf [<https://perma.cc/MT4D-NU6M>] (“Energy efficiency resources are included in the PJM Capacity Market. . . . The total MW of energy efficiency resources committed increased by 10.1 percent from 2,296.3 MW in the 2019/2020 Delivery Year to 2,528.5 MW in the 2020/2021 Delivery Year.”); *2020 State of the Market Report for the MISO Electricity Market XVIII*, POTOMAC ECON. (2021), https://www.potomaceconomics.com/wp-content/uploads/2021/05/2020-MISO-SOM_Report_Body_Compiled_Final_rev-6-1-21.pdf [<https://perma.cc/W7AX-H892>] (“The quantity of [energy efficiency] participating in the PRA has been growing rapidly and is playing a more pivotal role in satisfying MISO’s resource adequacy needs.”). In 2021, a record amount of energy efficiency cleared for sale into PJM’s capacity market. PJM, 2022/2023 RPM BASE RESIDUAL AUCTION RESULTS (PJM #5154776) (2021), <https://www.pjm.com/-/media/markets-ops/rpm/rpm-auction-info/2022-2023/2022-2023-base-residual-auction-report.ashx> [<https://perma.cc/LZ3X-NBC9>] (noting that “[o]f the 5,056.8 MW of energy efficiency that offered into the 2022/2023 [Base Residual Auction], 4,810.6 MW cleared in the auction”). Energy efficiency resources are expected to continue to participate in the ISO-NE capacity market. See *The Role of ISO New England and the Region’s Rapidly Changing Energy Resource Mix*, ISO-NE slide 7, 18 (Oct. 19, 2020), <https://www.mass.gov/doc/iso-ne-plymouth/download> [<https://perma.cc/GBM5-DB4D>] (noting that ISO-NE currently has 2,630 MW of energy efficiency resources with obligations in the Forward Capacity Market).

into the wholesale electricity markets as the order requires the regional electricity markets to revise their tariffs to make it easier for distributed energy resources, including energy efficiency, to be sold in these markets. For example, FERC ordered the wholesale electricity market operators to revise their market rules to allow aggregators of energy efficiency and other distributed energy resources to bid in these resources, with some exceptions.¹⁸⁹ Allowing in aggregators enables private actors to bundle the electricity use avoided through many small energy efficiency initiatives—such as installing efficient lighting and appliances in residential homes—that would be too insignificant individually to sell into the wholesale electricity markets, given the minimum size requirements for participating in these markets. There is, however, some opposition to the sale of energy efficiency in the wholesale capacity markets.¹⁹⁰ This opposition is related, in part, to a debate about whether energy efficiency is best accounted for in electricity markets as a reduction in demand or as a source of supply; sales of energy efficiency into the markets assume that it is a source of supply that can be quantified. When sold into a capacity market, energy efficiency provides another way, in addition to traditional power generation, to ensure that demand and supply for electricity match in the future. In so doing, the participation of energy efficiency in the capacity markets may reduce the need to build new power generation and transmission facilities and lower the cost of power.¹⁹¹

189. FERC Order No. 2222, *supra* note 2. The order “define[s] a distributed energy resource as any resource located on the distribution system, any subsystem thereof or behind a customer meter. These resources may include, but are not limited to, electric storage resources, distributed generation, demand response, energy efficiency, thermal storage, and electric vehicles and their supply equipment.” *Id.* at ¶ 67,095 n.1.

190. In PJM, MISO and ISO-NE, market monitors have recommended eliminating the participation of energy efficiency as a supply resource in the capacity market. *State of the Market Report for PJM*, *supra* note 188, at 339 (“The MMU recommends that energy efficiency MW not be included in the PJM Capacity Market. The measurement and verification protocols for energy efficiency are too imprecise to rely on as a source of capacity. Effective energy efficiency measures reduce energy usage and capacity usage directly. The reduced market payments are the appropriate compensation.”); *2020 State of the Market Report for the MISO Electricity Market XVIII*, *supra* note 188, at ix, xxi (2021) (recommending that MISO “[r]emove eligibility for energy efficiency to sell capacity” and “[disqualify] energy efficiency from selling capacity in the [Planning Resource Auction]”); *2020 Assessment of the ISO New England Electricity Markets*, POTOMAC ECON. 16 (2021), <https://www.iso-ne.com/static-assets/documents/2021/06/iso-ne-2020-emm-report-final-6-18-21.pdf> [<https://perma.cc/L8PJ-MFVT>] (recommending that ISO-NE account for energy efficiency in its Forward Capacity Market “as a reduction in load instead of as a supply resource”). For reasons for allowing the sale of energy efficiency as a source of electricity supply into the wholesale capacity markets, see Spees et al., *supra* note 186.

191. See Spees et al., *supra* note 186. FERC has previously recognized benefits from the sale of energy efficiency into capacity markets. See, e.g., PJM Interconnection, L.L.C., 126 FERC ¶ 61,275, p. 131 (2009) (“The Commission finds PJM’s proposal [to enable] EE resources [to participate in the capacity market] reasonable and will accept it. Under PJM’s current wholesale market structure, many retail customers who install energy efficiency measures do not capture the capacity benefit of the resources they install.”).

Energy efficiency is one type of distributed energy resource (DER). In *FERC v. Electric Power Supply Ass’n*, 577 U.S. 260 (2016), the Supreme Court upheld a FERC rule that sought to boost wholesale market participation of demand response, another type of DER, by requiring that the markets compensate demand response at the same level as traditional sources of electricity supply. Energy efficiency might be regarded as a permanent and passive form of demand response; while demand response programs reduce electricity consumption in peak periods, energy efficiency permanently reduces demand for electricity. On *FERC v.*

We are not aware of any voluntary markets for energy efficiency, but such markets could emerge given the growth forecasts for other voluntary markets, including the carbon offset and green power markets.¹⁹² Voluntary markets for energy efficiency would likely emerge in a decentralized manner in response to demand from private actors interested in purchasing energy efficiency resources to meet voluntary pledges that they cannot achieve through their own energy savings measures, rather than government mandates to increase energy efficiency. There is also the potential that utilities subject to regulatory requirements to improve energy efficiency could be permitted to purchase offsets from voluntary markets to meet their compliance obligations.¹⁹³ A lack of clarity about who initially owns energy efficiency might stifle the development of voluntary markets for energy efficiency attributes, and uniformity in rules across regulated and unregulated markets would likely help to stimulate greater participation on both fronts.

We argue that energy efficiency attributes should be allocated using a first-in-time rule. The desirability of a first-in-time rule for energy efficiency is suggested by the fact that the parties selling energy efficiency into FERC-regulated wholesale capacity markets appear to accept it as a means of initially allocating rights among themselves. Thus, this Article might be regarded as explaining the logic of a first-in-time rule in contexts where it is already used and providing an argument for extending a first-in-time rule to other contexts where markets in energy efficiency are deemed socially desirable. We begin by explaining why we support a first-in-time rule, and then discuss how the allocation resulting from that rule might bind third parties in different types of markets where energy efficiency is, and could be, sold. To emphasize the relevance of the Article's framework for creating property rights beyond energy efficiency, this Part concludes by discussing how the framework might be helpful in initially allocating property rights in water savings and attributes associated with the production and disposal of smartphones.

A. Identifying an Initial Owner

As mentioned in the introduction to this Article, multiple parties might theoretically claim the avoided electricity use when a refrigerator in a home is replaced with a more energy-efficient model. For example:

Electric Power Supply Ass'n, see Matthew R. Christiansen, *FERC v. EPSA: Functionalism and the Electricity Industry of the Future*, 68 STAN. L. REV. ONLINE 100 (2016).

192. Barry Friedman, Lori Bird & Galen Barbose, *Considerations for Emerging Markets for Energy Savings Certificates*, NAT'L RENEWABLE ENERGY LAB'Y 2, 22-23 (2008), <https://www.nrel.gov/docs/fy09osti/44072.pdf> [<https://perma.cc/8WX3-SC9N>]; Blaufelder et al., *supra* note 160; HEETER & O'SHAUGHNESSY, *supra* note 163. Over 300 companies have pledged to use only renewable energy; these companies might have an easier time meeting this pledge if they reduce the amount of energy that they consume. *RE100 Climate Group*, <https://www.there100.org> [<https://perma.cc/UCZ7-NYNC>].

193. Given the regulatory diversity of states with EERS, future voluntary trading programs could arise in different ways: parallel to regulatory markets in states with mandatory EERS; for states with non-binding EERS, in state-operated voluntary markets; or even in the absence of state EERS altogether.

The manufacturer of the more energy-efficient fridge might argue that it owns the energy efficiency attribute. It might appeal to the principle of accession, arguing that the avoided energy is closely connected to the refrigerator that it made, and that it sold only the fridge and not the distinct asset of the energy efficiency when it sold the refrigerator to the distributor or retailer who then sold it to the homeowner. The manufacturer also might invoke the labor theory, arguing that it was the manufacturer's "labor" in manufacturing the refrigerator that created the efficiency.

The homeowner might claim the avoided energy use based on the time that the homeowner invested in choosing the more energy-efficient appliance, paying for the appliance, and installing and using it. In making this argument, the homeowner might seem to be appealing to the "labor" principle. The homeowner would be arguing that they created the energy efficiency through the time they took to buy and install the appliance, the funds they used to pay for the appliance, and their actual use of the energy-efficient appliance rather than a more energy-consuming one. The homeowner also might appeal to accession, arguing that they own the energy efficiency because they own the fridge.

The retailer might argue that it created the efficiency by marketing the more energy-efficient refrigerator to the homeowner.

The installer might argue that its labor is responsible for the avoided energy use because it hauled away the old inefficient fridge and plugged in the new one.

If the homeowner borrowed money to finance the purchase of the refrigerator, the lender might argue that it owns the avoided energy use because it provided the funds that enabled the homeowner to purchase the new refrigerator and have the old one carted away.

The avoided energy use also might be claimed by an aggregator that bundles the energy efficiency attributes from this refrigerator and many others into a package that is sufficiently large and reliable to meet the minimum size and performance standards of the market covering the territory where the fridges are located. This aggregator might appeal to a first-in-time principle, arguing that it is the first party to have assembled the energy efficiency attributes from the fridge into a marketable format.

The electric utility¹⁹⁴ serving the home with the new refrigerator might argue that the utility owns the energy efficiency because it ran a public service campaign to raise consumer awareness of the benefits of buying energy efficiency appliances and perhaps has a rebate program that refunds to consumers a small part of the cost of purchasing energy-efficient appliances. The utility's argument might be analogized to an argument rooted in labor, with the utility claiming the property right based on its labor (or investment) in the public service campaign and rebate program.¹⁹⁵

194. Although there are various types of electric utilities, the utility's argument likely would not vary based on whether it is owned by investors or the public, for example.

195. Electric utility programs to reduce customer energy started in the 1970s. See Dan York, Patti Witte, Seth Novak & Marty Kushler, *Three Decades and Counting: A Historical Review and Current*

1. Allocating Ownership Based on a First-in-Time Rule

We propose that the energy efficiency attribute be initially allocated to the first party to present the attribute for sale in a format that can be sold into the market. Under this first-in-time rule, the party awarded ownership could be any actor—a manufacturer, an aggregator, a collective of homeowners, a utility, a nonprofit, etc.—provided the party appropriately presents the market with the energy efficiency in a useable format that meets the minimum size, performance and other standards of the market.¹⁹⁶ Once the attribute is initially allocated to a unique party under a first-in-time rule, the scope of the bundle of sticks that ownership conveys could be defined. For example, the bundle might entitle the owner to sell the attribute, but not allow the owner to require others to achieve the energy efficiency.¹⁹⁷ The content of the bundle of sticks comprising ownership is a distinct issue from the question of how the bundle is initially acquired, which is our primary concern in this Article.

What does it mean to be the first to present the market with energy efficiency for sale in a useable format? In broad terms, we propose that it means being the first to offer for sale an energy efficiency resource that meets the market's standards for sale, with proof of having contracted for the resource from the other immediately identifiable parties that might plausibly claim the resource.¹⁹⁸ The offer presumably would need to define such factors as: (i) how the party contracted with other plausible claimants to the resource; (ii) the bounds of the resource, including the sources of the energy efficiency (e.g., lightbulbs or

Assessment of Electric Utility Energy Efficiency Activity in the States, AM. COUNCIL FOR AN ENERGY EFFICIENT ECON. (June 2012), <https://www.aceee.org/sites/default/files/publications/researchreports/u123.pdf> [<https://perma.cc/6WDE-C8N5>]. Notably, in a 2015 order, FERC expressly stated that other entities, not just utilities, can own energy efficiency attributes and participate in wholesale electricity markets. Midwest Independent Transmission System Operator, Inc., 153 FERC ¶ 61,229 (2015) at 255, https://www.ferc.gov/sites/default/files/2020-05/E-11_29.pdf [<https://perma.cc/2VZU-99TQ>] (“We do not consider it reasonable to restrict the ownership or contractual rights to Energy Efficiency Resources to the LSE [Load Serving Entity] making the peak demand forecast. Entities other than LSEs, such as industrial customers, can own Energy Efficiency Resources and we see no reason to foreclose these entities from participation in MISO’s resource adequacy plan. For this reason, we consider it to be unreasonable to bar market participants from offering Energy Efficiency Resources into MISO’s resource adequacy plan.”).

196. For example, there are minimum size thresholds for bidding in distributed energy resources, including energy efficiency, into the wholesale electricity markets. FERC Order No. 2222, *supra* note 2, at ¶ 171 (requiring each RTO/ISO to “implement a minimum size requirement not to exceed 100 kW for all distributed energy resource aggregations”).

197. Also, the bundle might only contain rights that may be asserted against private parties, not against the government under the Takings Clause as is likely the case with many property rights in environmental attributes.

198. We see the contracts as defining the resource and enabling the party that wants to sell it to get the agreement of others it is contracting with that it owns the resource, not as *transferring* the resource to the party that wants to sell it. In other words, the contracts serve as a form of notice to the other parties that a particular resource is being claimed. We suggest that a party should be expected only to have contracted with the immediately identifiable parties with plausible claims because it would likely be impractical for them to contract with everyone who might claim ownership. As technology evolves, the number of people who might be considered plausible claimants with whom the party should contract might change.

refrigerators); (iii) the geography where the energy efficiency will be achieved; (iv) the time period over which the efficiency will be achieved; and (v) measurement and verification protocols for the resource. Moreover, as just mentioned, the offer would have to satisfy the minimum size and other performance standards of the market (or the buyer if the exchange is bilateral).

The exact form in which the party presents its claim will likely differ depending on the market. In some of the FERC-regulated wholesale capacity markets into which energy efficiency is sold, parties bidding in energy efficiency from a source and geography must confirm to the market operators that the parties own the energy efficiency being bid in.¹⁹⁹ To help establish ownership, parties in practice presumably contract with other immediately plausible claimants. In the regulated French market for white certificates described in Part II, it seems that the parties claiming the certificates must present contracts delineating ownership of the energy efficiency among potential claimants to a regulator who then authenticates the certificate. If private actors were to begin selling energy efficiency voluntarily to other private actors outside of regulated markets, the potential buyers likely would dictate the form in which sellers would assert their claims.

Evolving technology also might influence what should be required to be the first to claim energy efficiency. The spread of smart and internet-connected devices might create new mechanisms for securing energy efficiency. For example, these devices might open up the possibility of contracting cost-effectively with households to buy and aggregate their individually small energy savings for sale at the larger scale that markets demand.

There are three reasons to favor a first-in-time rule for allocating ownership of energy efficiency. First, such a rule is likely to lead to more energy efficiency being sold. The rule creates a race to capture energy efficiency in a format that will enable the resource to be sold in markets. It should incentivize private parties to find innovative ways to identify and package energy efficiency measures from households and other sources for market use because it assigns ownership based on packaging the energy efficiency in a useable format. Because the first-in-time rule awards ownership based on the act of winning the race—not the status of being a manufacturer, an installer, a homeowner, utility, etc.—the first-in-time rule also opens the race to new entrants with no prior connection to energy

199. PJM requires that a seller of energy efficiency resources “owns, or has the contractual authority to control” the resources. PJM, OATT, Definitions C-D, <https://pjm.com/media/documents/merged-tariffs/oatt.pdf> [https://perma.cc/A5WQ-2HA4]; see also *Capacity Exchange User Guide*, PJM 26-27, 29 (2021), <https://www.pjm.com/-/media/etools/capacity-exchange/capacity-exchange-user-guide.ashx?la=en> [https://perma.cc/8SMG-ZV2S]. ISO-NE requires that a seller have an “Ownership Share.” ISO-NE Market Rule 1 § III.9.5.1(b), https://www.iso-ne.com/static-assets/documents/2014/12/mr1_sec_1_12.pdf [https://perma.cc/K95P-K3EV]. MISO requires that sellers have “ownership or equivalent contractual rights.” MISO, OATT § 69A.3.2, <https://docs.misoenergy.org/legalcontent/TariffAsFiledVersion.pdf> [https://perma.cc/E38Y-VUXP]. PJM and ISO-NE require that sellers of energy efficiency resources confirm their ownership of the resource. *Capacity Exchange User Guide*, *supra*; *Energy Efficiency Measure Database (EEM) User Guide*, ISO-NE (2017), https://www.iso-ne.com/static-assets/documents/2015/01/eem_database_user_guide.pdf [https://perma.cc/2PQQ-NJ3A].

efficiency, entrants who may have new ideas and financing for assembling energy efficiency.

Related to the point that anyone could be awarded ownership to energy efficiency, a first-in-time rule treats all parties that might have a claim to the energy efficiency on an equal footing. It avoids choosing a “winner” up front and promotes competition to realize the goal of identifying and packaging novel resources for different markets.

As in any situation where parties are racing to acquire a resource, parties with more resources may have an advantage because they can invest in the technology to be the first to claim a resource.²⁰⁰ However, it is important to recognize that their advantage could be short-lived. New technologies that lower the cost of assembling energy efficiency may emerge, enabling less-resourced parties to defeat established players and win the race to meet market requirements for energy efficiency. For example, innovations in consumer technologies (such as the smart technologies mentioned above) might enable homeowners with energy-efficient fridges to join together on an electronic platform and satisfy the market’s demands for energy efficiency. Alternatively, entrepreneurs might develop technologies for packaging the homeowners’ avoided energy use that compensate homeowners, similar to the way in which demand response is aggregated.²⁰¹ A virtue of a first-in-time rule is that it awards initial ownership based on satisfying the market’s demands, allowing new parties to win the race for ownership, and encouraging new parties to develop innovative approaches to capturing energy efficiency. On the other hand, other principles that might be used to initially allocate energy efficiency might award it to better-resourced parties without providing opportunities for innovators to become initial owners and expand the supply of energy efficiency through their efforts.

Second, a first-in-time rule is reasonably straightforward to apply. To be sure, we are only sketching the bare outlines of what a party would be required to do to be deemed the first to have claimed the resource, and more work would have to be done to elaborate the rule for the novel contexts in which it would be applied. In elaborating what must be done to win the race, it is important to properly incentivize parties to identify and claim the energy efficiency that the market seeks.²⁰² What the winner must do to win the race should also establish a clear endpoint for the race so that the race is not protracted.²⁰³ Assuming there is

200. The risk that a first-in-time rule could favor parties with more resources is further discussed above in Section II.B.1.a.

201. See, e.g., Herman K. Trabish, *How Aggregated DERs Are Becoming the New Demand Response*, UTILITY DIVE (July 20, 2016), <https://www.utilitydive.com/news/how-aggregated-ders-are-becoming-the-new-demand-response/422725> [<https://perma.cc/2KF4-XKAD>]. For a comparison of demand response and energy efficiency, see *supra* note 191.

202. As mentioned in Section II.B.1.a, the rules for winning the race must align with the goals for the existence of the race. If the goal is to promote energy efficiency, the parties racing must be encouraged to identify energy efficiency, which is why we mention the need for measurement and verification protocols in describing what would be required to win the race. These protocols are important for establishing the existence of the resource being claimed.

203. Section II.B.1.a discusses in general terms the risks of a protracted race leading to wasteful racing behavior.

a means of informing other actors that energy efficiency for a set of energy efficiency measures in a territory is claimed, the rule should inform other private actors when the race is over and avoid wasteful duplication of efforts to propertize the same energy efficiency.²⁰⁴

Third, although there are risks in allocating some resources using a first-in-time rule, energy efficiency is not a resource prone to the “pathologies of first possession,”²⁰⁵ such as the tragedy of the commons. Energy efficiency is not a finite (or slowly renewable) resource, such as ocean fish, at risk of being over-used by encouraging a race to capture. On the contrary, energy efficiency is widely considered to be a plentiful resource that private and public actors have been slow to seize, even though reducing energy use would save them money.²⁰⁶ For decades, many governments have been encouraging reductions in electricity use; increasing energy efficiency will continue to be important as jurisdictions electrify vehicles and building uses, such as cooking, in an effort to decarbonize. The more people reduce their energy use, the less it will be necessary to build new renewable energy facilities to satisfy growing demand for electricity as vehicles and buildings are fully electrified. A race to spur improvements in energy efficiency would help to reduce GHG emissions, benefit the electricity system by reducing the need to build new power generation and transmission facilities, and lower energy costs for consumers.

2. Alternatives Rules for Allocating Ownership

Analysis of some of the alternatives to a first-in-time rule helps to strengthen the case for using such a rule for energy efficiency.

a. Accession

As described above, the principle of accession might be used to allocate ownership to energy efficiency. The principle seems most likely to be invoked by the manufacturers of energy-efficient appliances, on the basis that the efficiency is closely connected to the appliances, which the manufacturer is the first to own.²⁰⁷ The generic concerns with the principle of accession mentioned

204. Supplementary rules might be developed to deal with a (likely rare) scenario where two or more parties have equally valid claims to be the first to claim an energy efficiency resource.

205. We borrow the phrase from Merrill, *supra* note 70, at 482.

206. Ralph Cavanagh, *Ending Carbon Pollution: The Energy Efficiency Imperative*, NRDC (Feb. 16, 2021), <https://www.nrdc.org/experts/ralph-cavanagh/ending-carbon-pollution-energy-efficiency-imperative> [<https://perma.cc/Y8XW-W4VU>]; Steven Nadel & Lowell Ungar, *Halfway There: Energy Efficiency Can Cut Energy Use and Greenhouse Gas Emissions in Half by 2050*, AM. COUNCIL. FOR AN ENERGY EFFICIENT ECON., <https://www.aceee.org/sites/default/files/publications/researchreports/u1907.pdf> [<https://perma.cc/E937-H78F>].

207. A homeowner also might invoke accession, arguing that the energy efficiency is created once they install the fridge, and since they own the fridge, they also own the energy efficiency it generates. Under the first-in-time rule we recommend, homeowners would in theory be able to claim the energy efficiency if they met the market’s requirements for selling it, including having a sufficient amount of energy efficiency and measurement and verification protocols.

above seem applicable in this context. For example, it is not clear why the value of the energy efficiency should accrue to appliance manufacturers for free (as accession provides), even if there is a widespread intuition that the efficiency is closely connected to the appliances, which ultimately come to be owned by consumers. If the manufacturer is motivated and well-positioned to bring the efficiency to market, the first-in-time rule would allow the manufacturer to do so and obtain initial ownership of the resource. The difference between the first-in-time and accession rules is that the former would reward the manufacturer with ownership based on contributing to the policy goal of bringing the resource to the market, not automatically based on the manufacturer's status as the initial owner of the appliances. Thus, the first-in-time rule seems more aligned with the societal goal of enhancing energy efficiency.²⁰⁸

b. The Highest Bidder

Ownership of energy efficiency attributes also might be initially assigned through auctions that award it to the highest bidder, similar to the FCC auctions of spectrum. To allocate the resource by auction there would need to be an entity that could design and implement the auctions, such as a regulatory body akin to the FCC. Since they already operate sophisticated markets, the Regional Transmission Organizations (RTOs) and Independent Systems Operators (ISOs) might in theory auction rights to bundle household energy efficiency in the geographic area they serve and sell these bundles into their wholesale markets, assuming that the RTOs/ISOs were capable of identifying, measuring, and quantifying such resources.²⁰⁹ Auctions would require that claimants pay some of the value they could be expected to realize from household efficiency measures to the wholesale electricity markets, which might be justified on the basis that household energy efficiency is a socially-created resource whose value should not be solely appropriable by a single initial owner.

However, there are important grounds for skepticism about the desirability of using auctions to allocate initial ownership to energy efficiency for the purpose of getting it into the wholesale electricity markets. Using auctions likely would be inconsistent with FERC's goal of encouraging private actors to develop innovative approaches to capturing energy efficiency and other distributed

208. In practice, a first-in-time rule might lead to the same result as accession. For example, a manufacturer might win initial ownership of energy efficiency based on ownership of the fridge (under accession), and if the manufacturer is the first to meet the market's requirements for energy efficiency (under first-in-time). However, the grounds for winning differ under the two rules, and this matters. First-in-time leaves open the possibility that a different party—such as homeowners, aggregators or others—could win initial ownership in another circumstance based on being the first to claim the resource as the market demands. Under accession, once a particular category of actor (such as the manufacturer) is seen as the owner based on their ownership of something else, then that category is the initial owner going forward.

209. Financial transmission rights are currently auctioned in several RTO/ISO markets. Elise Caplan, *Understanding—and Reimagining—Financial Transmission Rights*, AM. PUB. POWER ASS'N (Jul. 15, 2020), <https://www.publicpower.org/periodical/article/understanding-and-reimagining-financial-transmission-rights> [https://perma.cc/3KW6-TQKE].

energy resources for participation in the wholesale electricity markets.²¹⁰ Requiring parties to buy the right to bundle household energy efficiency in a territory would establish a costly barrier that might discourage new entrants from trying their hand at packaging energy efficiency for sale in the wholesale markets. The parties most likely to bid in an auction for the right to package energy efficiency might be existing deep-pocketed electricity industry incumbents with the financial means to lock up rights to package household energy efficiency; the small players that might enter a race set up under a first-in-time rule might be discouraged by the price that auctions would impose. While a party would have to compete with others in the auction, the parties that purchased the auctioned off rights presumably would then have exclusive rights to harness efficiency within a specified territory, and thus not have to race to capture the efficiency within that territory.

Auctions for the right to harness household energy efficiency for sale in the wholesale markets also might be impractical for these markets to administer. Market operators might have difficulty defining the scope of the rights that would be auctioned to provide bidders with certainty about the rights they would acquire, while still incentivizing entities to innovate to capture novel forms of energy efficiency. There is a tension with relying on a centralized allocation system, such as an auction, to allocate rights to a novel attribute that is subject to unpredictable expansion.²¹¹ A first-in-time rule maintains the incentive to innovate. It is instructive that some of the supporters of the FCC's current use of auctions to allocate spectrum nonetheless defend the historical use of a first-in-time rule to allocate the spectrum in the early twentieth century at the formative stage of radio broadcasting, when less was known about the spectrum.²¹²

c. Labor

The labor theory and the closely related principles that ownership should be initially allocated to the party that created or paid for the resource could be invoked by several actors, including the manufacturer, the retailer, the installer, the homeowner, the lender, or the electric utility. One difficulty with this "labor" family of principles is that they are indeterminate. Energy efficiency is likely best viewed as a socially created resource, created by all of the listed parties and others: the homeowner contributes by buying the appliance, the manufacturer by making it, the retailer by selling it, the lender by financing it, the utility to the extent it has raised awareness of the benefits of reducing electricity consumption or sought to incentivize energy efficiency, etc. Relying on the labor family of

210. For evidence that FERC is promoting the introduction of distributed energy resources to encourage innovations that will "enhance competition and ensure just and reasonable rates," see FERC Order No. 2222, *supra* note 2, at ¶ 141 (prohibiting RTOs/ISOs from prohibiting "any particular type of distributed energy resource technology from participating in distributed energy resource aggregations" to avoid establishing "a barrier to entry for emerging or future technologies").

211. *See supra* note 142.

212. *See, e.g.,* Hazlett, *supra* note 86.

principles would require dividing ownership interests among the multiple actors who contributed to the creation of the resource in proportion to their contributions. Introducing multiple initial owners likely would complicate getting the resource to market, as consent from all owners would be necessary. Moreover, as already mentioned, the first-in-time rule would allow any of the parties with a claim based on labor or a related principle, either singly or in combination, to obtain initial ownership by being the first to lay claim to the resource.

B. Binding Third Parties to the Initial Allocation

Once energy efficiency resources are initially allocated to a unique owner, it is necessary to bind third parties to that allocation to establish an *in rem* property right.

In the regulated markets where energy efficiency is currently traded, a hybrid approach, combining top-down and bottom-up elements, currently seems to be used to bind the broader community to the choice of an initial owner. As explained in Section IV.A, when parties bid energy efficiency into the wholesale capacity markets, the parties define the resource that they are bidding in and, in some markets, confirm their ownership, presumably relying on contracts they have negotiated with other immediately identifiable plausible claimants. While the market operators may not see themselves as doing this, by accepting a party's bid, the market operators implicitly confirm the bidder's ownership of the energy efficiency and bind others to it, by eliminating the ability of others to bid the same resource into the market.

In the French market for white certificates described in Section II.B.2.c, private parties similarly appear to define the energy efficiency resource and contract with other immediately plausible claimants to lay claim to it. Then, private parties have their energy efficiency certified by a government regulatory agency. By certifying the energy efficiency, the agency validates the private party's claim to the energy efficiency, cutting off other claims for that resource, and therefore binding the broader community to the allocation the parties initially settled on as a matter of contract.

There are sound reasons for relying on a hybrid approach to bind third parties to the initial allocation of ownership that is sold into regulated markets, such as the wholesale electricity markets and the markets for white certificates. For one, private parties are likely to be better at defining a relatively novel resource such as energy efficiency than the regulators. The private parties are the actors finding the resource, and they are therefore better informed about its contours. Private parties also are well-positioned to contract with other private parties to delineate the geographic scope of the avoided energy use, and the sources of the avoided use, that the private parties have found and would like to sell.

However, private parties are unlikely to be able to bind the community as a whole to an allocation of energy efficiency through contracts alone. As Locke recognized hundreds of years ago, and modern property scholars continue to emphasize, it is difficult if not impossible to create an *in rem* property right through contracts.²¹³ The number of people with whom it is necessary to contract to secure a right that binds the “whole world” is too large. Market operators, such as the actors that certify white certificates or operate the wholesale electricity markets, thus play a valuable role in binding third parties with whom it is too costly to contract. By accepting a bid, or issuing a certification, the market operators cut off the potential for other parties to claim the energy efficiency.

Furthermore, in regulated markets, the market operators are likely to be well-positioned to provide third parties with notice of the claims that the operators have accepted. Subject to protections for confidential business information, market operators might choose to provide this information to third parties informally, for example by responding to questions about whether a resource is already participating in a market. Alternatively, market operators might choose to develop a registry to efficiently make available high-level information about the energy efficiency that has already been propertized and sold.²¹⁴ The design of a registry would need to respect practical constraints on collecting information about the measures generating energy efficiency and legal protections for confidential business information. The provision of information would reduce the costs to third parties of respecting existing property rights, and channel efforts to identify new energy efficiency to unclaimed resources. By making information available about existing claims, market operators also avoid the need to deal with duplicative claims to the same resource. In sum, in regulated markets, it makes sense to bind third parties to an initial allocation of energy efficiency through a combination of resource definition by the private actors claiming the energy efficiency and confirmation of their claims by market operators.

As mentioned above, we are not aware of any voluntary, unregulated markets in energy efficiency. If such markets were to emerge, they by definition would not be overseen by regulators with the authority to bind third parties to an initial allocation of energy efficiency. Property rights would have to be allocated in a decentralized, bottom-up fashion relying on private rules and norms. As discussed in Part II, there are voluntary markets in some environmental attributes, such as carbon credits. The existence of these markets suggests the potential for private parties to package attributes into binding property rights, using intermediaries such as verifiers to build norms that lead people to respect the rights.

213. See *supra* note 149.

214. On the functions of registries, see BENITO ARRUÑADA, INSTITUTIONAL FOUNDATIONS OF IMPERSONAL EXCHANGE: THEORY AND POLICY OF CONTRACTUAL REGISTRIES (2012).

C. Other Potential Applications

This Article illustrates how various principles and techniques for initially allocating ownership might be applied using the example of energy-efficiency attributes. There are other environmental attributes to which these principles and techniques might be applied.

Returning to the distinction drawn in Part I between avoided and active consumption, it might be worth exploring whether attributes that involve the non-use of a resource are generally best awarded using a first-in-time rule like the one we have suggested for energy efficiency. Using a first-in-time rule might create a race to avoid consuming resources, and thereby benefit the environment. Consider, for example, the avoided consumption of water, a potentially measurable attribute for which there might be market demand in jurisdictions where water is scarce. In these areas, firms that are large water users, such as beverage or denim manufacturers, might voluntarily reduce their water consumption or be required by the government to do so.²¹⁵ Government or voluntary caps on water consumption might lead water savings to become valuable. The firms might be able to reduce some water use at their facilities, but they also might seek to meet some of the water savings goals by paying others who can reduce water use more cheaply to do so. Other firms, or homeowners who can reduce the amount of water that they use to water their lawns, might seek to sell the avoided water consumption, raising the question of who initially owns the avoided water consumption. Under a first-in-time rule, the party that can measure and package the avoided water consumption to the satisfaction of the buyer would be the initial owner, potentially motivating a race to avoid consuming water if there is sufficient demand for avoiding water use.²¹⁶ Third parties might be bound to the allocation of rights in water savings through the development of norms if the rights and markets were created privately, or by government (and potentially private) action if they were established in a top-down manner.

While water savings and energy efficiency are relatively easy to fathom, there are other, less intuitive, environmental attributes that might be measured, allocated and sold if there were demand for them.²¹⁷ For example, there are many

215. Beth Gardiner, *Beverage Industry Works to Cap Its Water Use*, N.Y. TIMES (Mar. 21, 2011), <https://www.nytimes.com/2011/03/22/business/energy-environment/22iht-rbog-beverage-22.html> [<https://perma.cc/5D9F-B7ZY>]; *How Much Do Our Wardrobes Cost to the Environment?*, WORLD BANK (Sept. 23, 2019), <https://www.worldbank.org/en/news/feature/2019/09/23/costo-moda-medio-ambiente> [<https://perma.cc/HE4C-72HS>].

216. There is water law on similar questions. States have created rights to maintain water in streams. See *supra* note 103 and accompanying text. In Colorado, where prior appropriation is the basis for initially obtaining water rights, there is case law on whether a water rights holder who “creates” more water for human consumption by modifying the environment in the stream is entitled to a right in the water, or whether the water will be allocated to existing water rights holders from the stream based on priority. See, e.g., *R.J.A., Inc. v. Water Users Ass’n*, 690 P.2d 823 (Colo. 1984).

217. As mentioned above, there is no point in creating property rights or markets in an attribute for which there is no demand. Also, even if there is demand for an attribute, society might opt not to create

environmental harms associated with the proliferation of electronics, such as smartphones. The production of smartphones uses rare “elements like gold, cobalt or lithium.”²¹⁸ Mining for these and other elements pollutes water, clears land, and generates dangerous waste. Later in their lifecycles, smartphones can create water and soil pollution if the phones are improperly disposed of in landfills.²¹⁹ There are many ways that the environmental problems associated with phones could be addressed; one way might be to think of the manufacture and proper disposal of phones as giving rise to environmental attributes.

The use of lithium to manufacture phones involves active consumption of that resource; governments might seek to cap the amount of lithium that manufacturers could use in making phones, and allocate allowances to use that limited quantity of lithium. Similar to the way that some cap-and-trade programs initially allocate permits to release a quantity of emissions, the government might auction the limited number of permits to use lithium using the highest bidder principle. The government could bind third parties to the auctioned allocation of rights in a top-down manner. To address the harms from improper disposal of smartphones, the benefits of recycling smartphones theoretically could be isolated and denominated in “recycling credits.” These credits would be for avoided consumption: the water and soil pollution that is avoided by not landfilling smartphones, and the mining that might be avoided by recovering and reusing the minerals in old smartphones. Certified recyclers might issue recycling credits to people or firms that are the first to bring smartphones to the recyclers.²²⁰ The government might stimulate a market for the recycling credits by requiring that retailers, manufacturers or other actors in the smartphone supply chain provide the government with a certain quantity of recycling credits every year. The credits might be recognized by third parties if the credits are distributed by the certified recyclers pursuant to rules established by the recyclers or the government, or a combination of them in a hybrid manner. In setting out these examples of how attributes might be recognized to address the environmental harms of smartphones, we do not mean to suggest that commodifying these attributes is necessarily the best means of dealing with e-

property rights or markets because of concerns about the implications of commodifying the attribute. *See supra* note 68 and Section I.C.

218. Bruno Martín, *The Hidden Environmental Toll of Smartphones*, OPEN MIND BBVA (Feb. 24, 2020), <https://www.bbvaopenmind.com/en/science/environment/the-hidden-environmental-toll-of-smartphones> [<https://perma.cc/7XLU-5NCJ>].

219. *Id.*; see also Renee Cho, *What Can We Do About the Growing E-waste Problem?*, COLUM. CLIMATE SCH.: STATE OF OUR PLANET (Aug. 27, 2018), <https://news.climate.columbia.edu/2018/08/27/growing-e-waste-problem> [<https://perma.cc/Z3VA-PXJ6>] (noting that e-waste is infrequently recycled properly and is largely disposed of in landfills).

220. We refer to “certified” recyclers because it would be necessary to ensure that the recyclers taking the smartphones correctly recycle them to avoid harms to the environment in the U.S. and abroad. On some of the problems with relying on recycling to deal with e-waste, see, for example Cho, *supra* note 219. For a discussion of the utility of certifying recyclers, see *Certified Electronics Recyclers*, EPA, <https://www.epa.gov/smm-electronics/certified-electronics-recyclers> [<https://perma.cc/RWV3-JURK>].

waste from smartphones; there may well be superior approaches.²²¹ We provide these examples to illustrate that there are many environmental attributes that might be made the object of property rights using the principles and techniques outlined in Part II, if society deems it desirable to do so.

Conclusion

Historically, changes in technology have spurred changes to property rights. The invention of the airplane,²²² the development of radio broadcasting, and new fishing technologies²²³ all prompted the alteration of old understandings of property rights and the creation of new ones. As technology advances, it is becoming increasingly possible to isolate environmental resources that are hard to see and touch, such as actual and avoided carbon emissions, methane emissions from cows burping, and reductions in energy use. Establishing property rights in these attributes would encourage private parties to trade them and, in so doing, help achieve societal goals such as transitioning away from fossil fuels to avoid catastrophic climate change.

Although often caricatured as static and slow to change, property is continually evolving.²²⁴ This article has provided a menu of options for allocating new rights in environmental attributes that governments and private actors can use if they wish to realize the benefits afforded by technological innovation. Applying this menu of options, this Article has attempted to develop a rule for initially allocating the rights to energy efficiency attributes. As technology continues to evolve, options identified in the menu might be used to initially allocate rights to other newly measurable environmental attributes.
